# **ANDES Manual**

***Release 1.6.0***

**Hantao Cui**

**Mar 11, 2022**

# ANDES MANUAL

<b>1</b>	<b>Getting started</b>	<b>3</b>
1.1	Installation	3
1.1.1	Environment	3
1.1.2	Install ANDES	4
1.1.3	Updating ANDES	5
1.1.4	Performance Packages	6
1.2	Tutorial	6
1.2.1	Command Line Usage	7
1.2.2	Interactive Usage	16
1.2.3	I/O Formats	24
1.2.4	Per Unit System	27
1.2.5	Cheatsheet	27
1.2.6	Make Documentation	27
1.3	Test Cases	28
1.3.1	Directory	28
1.3.2	MATPOWER Cases	30
1.3.3	Performance	30
1.4	Parsers	32
1.4.1	PSS/E Dyr Parser	32
1.5	Config references	34
1.5.1	System	34
1.5.2	PFlow	35
1.5.3	TDS	36
1.5.4	EIG	36
1.6	Miscellaneous	37
1.6.1	Notes	37
1.6.2	Profiling Import	38
1.6.3	What won't not work	38
1.7	Frequently Asked Questions	38
1.7.1	Program Startup	38
1.7.2	General	38
1.7.3	Modeling	39
1.8	License	39
1.8.1	GNU Public License v3	39

<b>2</b>	<b>Examples</b>	<b>41</b>
2.1	Simulate and Plot . . . . .	41
2.1.1	Import and Setting the Verbosity Level . . . . .	41
2.1.2	Run Time-Domain Simulation . . . . .	42
2.1.3	Export and Plot Results . . . . .	43
2.1.4	Cleanup . . . . .	55
2.2	Working with Data . . . . .	55
2.2.1	Load System from an ANDES XLSX File . . . . .	55
2.2.2	Load System from PSS/E RAW and DYS Files . . . . .	57
2.2.3	Variables . . . . .	62
2.2.4	Cleanup . . . . .	65
2.3	Inspecting Models . . . . .	66
2.3.1	Inspect Model Equations . . . . .	66
2.3.2	Check model documentation . . . . .	67
2.4	Eigenvalue Analysis . . . . .	74
2.4.1	Run Eigenvalue Analysis . . . . .	74
2.4.2	Plotting in Z-Domain . . . . .	76
2.4.3	Report . . . . .	76
2.4.4	Cleanup . . . . .	97
2.5	Using CLI from Notebook . . . . .	97
2.5.1	The ! magic in iPython . . . . .	97
2.5.2	Set up on Windows . . . . .	98
2.5.3	Running Shell Commands . . . . .	98
2.5.4	Run a simulation . . . . .	99
2.5.5	Check the output 1st file . . . . .	103
2.5.6	Plot and save to file . . . . .	107
2.5.7	Display image . . . . .	108
2.5.8	Using xargs for index loop up . . . . .	108
2.5.9	Using xargs for index lookup . . . . .	109
2.5.10	Cleanup . . . . .	109
2.6	Batch Processing - Generate Cases . . . . .	110
2.6.1	Create Cases in Batch . . . . .	110
2.6.2	Parallel Simulation . . . . .	111
2.7	Batch Processing - in Memory . . . . .	116
2.7.1	Batch Power Flow Calculation . . . . .	116
2.7.2	Batch Time-Domain Simulation . . . . .	118
2.8	Changing Setpoints . . . . .	128
2.8.1	Step 1: Case Setup . . . . .	129
2.8.2	Step 2: Set the First Stop Time . . . . .	130
2.8.3	Step 3: Run Simulation . . . . .	130
2.8.4	Step 4: Apply the auxiliary power setpoints to TGOV1.paux0.v . . . . .	130
2.8.5	Step 5: Set Another New Setpoints and New Ending Time. . . . .	136
2.9	Load Frequency Control . . . . .	138
2.9.1	Tripping a Generator in the IEEE 14-Bus System . . . . .	138
2.9.2	Adjusting Load to Compensate for the Generation Loss . . . . .	142
2.10	Profile in Notebook . . . . .	147
2.10.1	Profiling with Python CProfiler . . . . .	147
2.10.2	Profiling with line_profiler. . . . .	150

2.10.3	Cleanup . . . . .	153
<b>3</b>	<b>Model references</b>	<b>155</b>
3.1	ACLine . . . . .	156
3.1.1	Line . . . . .	156
3.2	ACShort . . . . .	158
3.2.1	Jumper . . . . .	159
3.3	ACTopology . . . . .	160
3.3.1	Bus . . . . .	160
3.4	Calculation . . . . .	162
3.4.1	ACE . . . . .	162
3.4.2	ACEc . . . . .	163
3.4.3	COI . . . . .	164
3.5	Collection . . . . .	166
3.5.1	Area . . . . .	166
3.6	DCLink . . . . .	166
3.6.1	Ground . . . . .	167
3.6.2	R . . . . .	168
3.6.3	L . . . . .	169
3.6.4	C . . . . .	170
3.6.5	RCp . . . . .	171
3.6.6	RCs . . . . .	172
3.6.7	RLs . . . . .	173
3.6.8	RLCs . . . . .	175
3.6.9	RLCp . . . . .	176
3.7	DCTopology . . . . .	177
3.7.1	Node . . . . .	178
3.8	DG . . . . .	179
3.8.1	PVD1 . . . . .	179
3.8.2	ESD1 . . . . .	186
3.8.3	EV1 . . . . .	193
3.8.4	EV2 . . . . .	200
3.9	DGProtection . . . . .	207
3.9.1	DGPRCT1 . . . . .	207
3.9.2	DGPRCTExt . . . . .	213
3.10	DynLoad . . . . .	219
3.10.1	ZIP . . . . .	219
3.10.2	FLoad . . . . .	221
3.11	Exciter . . . . .	222
3.11.1	EXDC2 . . . . .	222
3.11.2	IEEEEX1 . . . . .	227
3.11.3	ESDC2A . . . . .	231
3.11.4	EXST1 . . . . .	235
3.11.5	ESST3A . . . . .	238
3.11.6	SEXS . . . . .	245
3.11.7	IEEET1 . . . . .	247
3.11.8	EXAC1 . . . . .	251
3.11.9	EXAC4 . . . . .	256

3.11.10	ESST4B	258
3.11.11	AC8B	264
3.11.12	IEEET3	271
3.11.13	ESAC1A	275
3.11.14	ESST1A	282
3.12	Experimental	288
3.13	FreqMeasurement	288
3.13.1	BusFreq	288
3.13.2	BusROCOF	290

ANDES is a Python-based free software package for power system simulation, control and analysis. It establishes a unique **hybrid symbolic-numeric framework** for modeling differential algebraic equations (DAEs) for numerical analysis. Main features of ANDES include

- a unique hybrid symbolic-numeric approach to modeling and simulation that enables descriptive DAE modeling and automatic numerical code generation
- a rich library of transfer functions and discontinuous components (including limiters, dead-bands, and saturation) available for prototyping models, which can be readily instantiated as multiple devices for system analysis
- industry-grade second-generation renewable models (solar PV, type 3 and type 4 wind), distributed PV and energy storage model
- comes with the Newton method for power flow calculation, the implicit trapezoidal method for time-domain simulation, and full eigenvalue calculation
- strictly verified models with commercial software. ANDES obtains identical time-domain simulation results for IEEE 14-bus and NPCC system with GENROU and multiple controller models. See the verification link for details.
- developed with performance in mind. While written in Python, ANDES comes with a performance package and can finish a 20-second transient simulation of a 2000-bus system in a few seconds on a typical desktop computer
- out-of-the-box PSS/E raw and dyr file support for available models. Once a model is developed, inputs from a dyr file can be readily supported
- an always up-to-date equation documentation of implemented models

ANDES is currently under active development. To get involved,

- Follow the tutorial at <https://andes.readthedocs.io>
- Checkout the Notebook examples in the [examples folder](#)
- Try ANDES in Jupyter Notebook [with Binder](#)
- Download the PDF manual at [download](#)
- Report issues in the [GitHub issues page](#)
- Learn version control with [the command-line git](#) or [GitHub Desktop](#)
- If you are looking to develop models, read the [Modeling Cookbook](#)

This work was supported in part by the Engineering Research Center Program of the National Science Foundation and the Department of Energy under NSF Award Number EEC-1041877 and the [CURENT](#) Industry Partnership Program. **ANDES is made open source as part of the CURENT Large Scale Testbed project.**

ANDES is developed and actively maintained by [Hantao Cui](#). See the GitHub repository for a full list of contributors.

## GETTING STARTED

### 1.1 Installation

ANDES can be installed in Python 3.6+. Please follow the installation guide carefully.

#### 1.1.1 Environment

##### Setting Up Miniconda

We recommend the Miniconda distribution that includes the conda package manager and Python. Downloaded and install the latest Miniconda (x64, with Python 3) from <https://conda.io/miniconda.html>.

Step 1: Open terminal (on Linux or macOS) or *Anaconda Prompt* (on Windows, **not the cmd program!!**). Make sure you are in a conda environment - you should see (base) prepended to the command-line prompt, such as (base) C:\Users\user>.

Create a conda environment for ANDES (recommended)

```
conda create --name andes python=3.7
```

Activate the new environment with

```
conda activate andes
```

You will need to activate the andes environment every time in a new Anaconda Prompt or shell.

Step 2: Add the conda-forge channel and set it as default

```
conda config --add channels conda-forge
conda config --set channel_priority flexible
```

If these steps complete without an error, continue to *Install Andes*.

## Existing Python Environment (Advanced)

This is for advanced user only and is **not recommended on Microsoft Windows**. Please skip it if you have set up a Conda environment.

Instead of using Conda, if you prefer an existing Python environment, you can install ANDES with *pip*:

```
python3 -m pip install andes
```

If you see a *Permission denied* error, you will need to install the packages locally with *--user*

### 1.1.2 Install ANDES

ANDES can be installed in the user mode and the development mode.

- If you want to use ANDES without modifying the source code, install it in the *User Mode*.
- If you want to develop models or routine, install it in the *Development Mode*.

#### User Mode

**Warning:** Please skip this section and install ANDES in the *Development Mode* if you want to modify ANDES code or receive unreleased development updates.

The User Model installation will install the latest stable version. In the Anaconda environment, run

```
conda install andes
```

You will be prompted to confirm the installation,

This command installs ANDES into the active environment, which should be called *andes* if you followed all the above steps.

---

**Note:** To use *andes*, you will need to activate the *andes* environment every time in a new Anaconda Prompt or shell.

---

#### Development Mode

This is for users who want to hack into the code and, for example, develop new models or routines. The usage of ANDES is the same in development mode as in user mode. In addition, changes to source code will be reflected immediately without re-installation.

Step 1: Get ANDES source code

As a developer, you are strongly encouraged to clone the source code using *git* from either your fork or the original repository:

```
git clone https://github.com/cuihantao/andes
```

In this way, you can easily update to the latest source code using `git`.

Alternatively, you can download the ANDES source code from <https://github.com/cuihantao/andes> and extract all files to the path of your choice. Although this will work, this is not recommended since tracking changes and pushing back code would be painful.

Step 2: Install dependencies

In the Anaconda environment, use `cd` to change directory to the ANDES root folder.

Install dependencies with

```
conda install --file requirements.txt
conda install --file requirements-dev.txt
```

Step 3: Install ANDES in the development mode using

```
python3 -m pip install -e .
```

Note the dot at the end. Pip will take care of the rest.

### 1.1.3 Updating ANDES

Regular ANDES updates will be pushed to both conda-forge and Python package index. It is recommended to use the latest version for bug fixes and new features. We also recommended you to check the [Release notes](#) before updating to stay informed of changes that might break your downstream code.

Depending you how you installed ANDES, you will use one of the following ways to upgrade.

If you installed it from conda (most common for users), run

```
conda install -c conda-forge --yes andes
```

If you install it from PyPI (namely, through `pip`), run

```
python3 -m pip install --yes andes
```

If you installed ANDES from source code (in the *Development Mode*), and the source was cloned using `git`, you can use `git pull` to pull in changes from remote. However, if your source code was downloaded, you will have to download the new source code again and manually overwrite the existing one.

In rare cases, after updating the source code, command-line `andes` will complain about missing dependency. If this ever happens, it means the new ANDES has introduced new dependencies. In such cases, reinstall `andes` in the development mode to fix. Change directory to the ANDES source code folder that contains `setup.py` and run

```
python3 -m pip install -e .
```

### 1.1.4 Performance Packages

---

**Note:** Performance packages can be safely skipped and will not affect the functionality of ANDES.

---

#### numba

---

**Note:** Numba is supported starting from ANDES 1.5.0 and is automatically installed for ANDES  $\geq 1.5.3$ . Please refer to the following for turning on Numba.

---

Numba allows numerical functions calls to be compiled into machine code. It can accelerate simulations by as high as 30%. The speed up is visible in medium-scale systems with multiple models. Such systems involve heavy function calls but rather moderate load for linear equation solvers. It is less significant in large-scale systems where solving equations is the major time consumer.

To install **numba**, run the following command in the terminal or Anaconda Prompt

```
python -m pip install numba
```

Numba needs to be turned on manually. Refer to the tutorial for editing ANDES configuration. To turn on numba for ANDES, in the ANDES configuration under [System], set `numba = 1` and `numba_cache = 1`.

Just-in-time compilation will compile the code upon the first execution based on the input types. When compilation is triggered, ANDES may appear frozen due to the compilation lag. The option `numba_cache = 1` will cache compiled machine code, so that the compilation lag only occurs once until the next code generation.

Code can be compiled ahead of time with

```
andes prep -c
```

It may take a minute for the first time. Future compilations will be incremental and faster.

## 1.2 Tutorial

ANDES can be used as a command-line tool or a library. The command-line interface (CLI) comes handy to run studies. As a library, it can be used interactively in the IPython shell or the Jupyter Notebook. This chapter describes the most common usages.

Please see the cheat sheet if you are looking for quick help.

## 1.2.1 Command Line Usage

### Basic Usage

ANDES is invoked from the command line using the command `andes`. Running `andes` without any input is equal to `andes -h` or `andes --help`. It prints out a preamble with version and environment information and help commands:

```

      _ _ _ _ _ | Version 1.3.4
    / _ \ _ _ _ _ | | _ _ _ _ | Python 3.8.6 on Linux, 03/17/2021 11:28:55 AM
  / _ \ \ | ' \ / _ \ / _ \ _ \ |
/_/_ \ _ \ _ \ | _ \ _ \ _ \ _ \ / _ \ | This program comes with ABSOLUTELY NO WARRANTY.

usage: andes [-h] [-v {1,10,20,30,40}]
           {run,plot,doc,misc,prepare,selftest} ...

positional arguments:
{run,plot,doc,misc,prepare,selftest}
    [run] run simulation routine; [plot] plot results;
    [doc] quick documentation; [misc] misc. functions;
    [prepare] prepare the numerical code; [selftest] run
    self test.

optional arguments:
-h, --help            show this help message and exit
-v {1,10,20,30,40}, --verbose {1,10,20,30,40}
                      Verbosity level in 10-DEBUG, 20-INFO, 30-WARNING, or
                      40-ERROR.

```

**Note:** If the `andes` command is not found, check if (1) the installation was successful, and (2) you have activated the environment where ANDES is installed.

The first-level commands are chosen from `{run,plot,doc,misc,prepare,selftest}`. Each command contains a group of sub-commands, which can be looked up with `-h`. For example, use `andes run -h` to look up the sub-commands for `run`. The most frequently used commands are explained in the following.

`andes` has an option for the program verbosity level, controlled by `-v LEVEL` or `--verbose LEVEL`, where level is a number chosen from the following: 1 (DEBUG with code location info), 10 (DEBUG), 20 (INFO), 30 (WARNING), 40 (ERROR), or 50 (CRITICAL). For example, to show debugging outputs, use `andes -v 10`, followed by the first-level commands. The default logging level is 20 (INFO).

### andes selftest

After the installation, please run `andes selftest` from the command line to test ANDES functionality. It might take a minute to run the full self-test suite. An example output looks like

```
test_docs (test_1st_system.TestCodegen) ... ok
test_alter_param (test_case.Test5Bus) ... ok
...
... (outputs are truncated)
...
test_pflow_mpc (test_pflow_matpower.TestMATPOWER) ... ok

-----
Ran 23 tests in 13.834s

OK
```

There may be more test than what is shown above. Make sure that all tests have passed.

**Warning:** ANDES is getting updates frequently. After every update, please run `andes selftest` to confirm the functionality. The command also makes sure the generated code is up to date. See [andes prepare](#) for more details on automatic code generation.

### andes prepare

The symbolically defined models in ANDES need to be generated into numerical code for simulation. The code generation can be manually called with `andes prepare`. Generated code are serialized to `~/.andes/calls.pkl` and dumped as Python code to `~/.andes/pycode`. In addition, `andes selftest` implicitly calls the code generation. If you are using ANDES as a package in the user mode (namely, you have not modified or updated ANDES code), you will not need to call it again.

---

**Note:** To developers: As of version 1.3.0, ANDES stores all generated Python code explicitly in `.py` files under the folder `~/.andes/pycode`. Priority is given to Python code when reloading for simulation.

---

Option `-q` or `--quick` (enabled by default) can be used to speed up the code generation. It skips the generation of  $\LaTeX$ -formatted equations, which are only used in documentation and the interactive mode.

Option `-i` or `--incremental`, instead of `-q`, can be used to further speed up the code generation during model development. `andes prepare -i` only generates code for models that have been modified since the last code generation.

---

**Note:** To developers: `andes prepare -i` needs to be called immediately following any model equation modification. Otherwise, simulation results will not reflect the new equations and will likely lead to an error.

---

## andes run

`andes run` is the entry point for power system analysis routines. `andes run` takes one positional argument, `filename`, along with other optional keyword arguments. `filename` is the test case path, either relative or absolute.

For example, the command `andes run kundur_full.xlsx` uses a relative path. It will work only if `kundur_full.xlsx` exists in the current directory of the command line. The commands `andes run /Users/hcui7/kundur_full.xlsx` (on macOS) or `andes run C:/Users/hcui7/kundur_full.xlsx` (on Windows) use absolute paths to the case files and do not depend on the command-line current directory.

---

**Note:** When working with the command line, use `cd` to change directory to the folder containing your test case. Spaces in folder and file names need to be escaped properly.

---

## Routine

Option `-r` or `-routine` is used for specifying the analysis routine, followed by the routine name. Available routine names include `pflow`, `tds`, `eig`: `pflow` for power flow - `tds` for time domain simulation - `eig` for eigenvalue analysis

`pflow` is the default if `-r` is not given.

## Power flow

Locate the `kundur_full.xlsx` file at `andes/cases/kundur/kundur_full.xlsx` under the source code folder, or download it from [the repository](#).

Change to the directory containing `kundur_full.xlsx`. To run power flow, execute the following in the command line:

```
andes run kundur_full.xlsx
```

The full path to the case file is also recognizable, for example,

```
andes run /home/user/andes/cases/kundur/kundur_full.xlsx
```

The power flow report will be saved to the current directory where ANDES is run. The report contains four sections: a) system statistics, b) ac bus and dc node data, c) ac line data, and d) the initialized values of other algebraic variables and state variables.

## Time-domain simulation

To run the time domain simulation (TDS) for `kundur_full.xlsx`, run

```
andes run kundur_full.xlsx -r tds
```

The output looks like:

```
Parsing input file </Users/user/repos/andes/tests/kundur_full.xlsx>
Input file kundur_full.xlsx parsed in 0.5425 second.
-> Power flow calculation with Newton Raphson method:
0: |F(x)| = 14.9283
1: |F(x)| = 3.60859
2: |F(x)| = 0.170093
3: |F(x)| = 0.00203827
4: |F(x)| = 3.76414e-07
Converged in 5 iterations in 0.0080 second.
Report saved to </Users/user/repos/andes/tests/kundur_full_out.txt> in 0.0036_
↪second.
-> Time Domain Simulation:
Initialization tests passed.
Initialization successful in 0.0152 second.
 0%|                                     | 0/100 [00:00<?, ?%/s]
  <Toggle 0>: Applying status toggle on Line idx=Line_8
100%|-----| 100/100 [00:03<00:00, 28.99%/s]
Simulation completed in 3.4500 seconds.
TDS outputs saved in 0.0377 second.
-> Single process finished in 4.4310 seconds.
```

This execution first solves the power flow as a starting point. Next, the numerical integration simulates 20 seconds, during which a predefined breaker opens at 2 seconds.

TDS produces two output files by default: a compressed NumPy data file `kundur_full_out.npz` and a variable name list file `kundur_full_out.lst`. The list file contains three columns: variable indices, variable name in plain text, and variable name in the *L<sup>A</sup>T<sub>E</sub>X* format. The variable indices are needed to plot the needed variable.

## Disable output

The output files can be disabled with option `--no-output` or `-n`. It is useful when only computation is needed without saving the results.

## Profiling

Profiling is useful for analyzing the computation time and code efficiency. Option `--profile` enables the profiling of ANDES execution. The profiling output will be written in two files in the current folder, one ending with `_prof.txt` and the other one with `_prof.prof`.

The text file can be opened with a text editor, and the `.prof` file can be visualized with `snakeviz`, which can be installed with `pip install snakeviz`.

If the output is disabled, profiling results will be printed to stdio.

## Multiprocessing

ANDES takes multiple files inputs or wildcard. Multiprocessing will be triggered if more than one valid input files are found. For example, to run power flow for files with a prefix of `case5` and a suffix (file extension) of `.m`, run

```
andes run case5*.m
```

Test cases that match the pattern, including `case5.m` and `case57.m`, will be processed.

Option `--ncpu NCPU` can be used to specify the maximum number of parallel processes. By default, all cores will be used. A small number can be specified to increase operation system responsiveness.

## Format converter

ANDES recognizes a few input formats and can convert input systems into the `xlsx` format. This function is useful when one wants to use models that are unique in ANDES.

The command for converting is `--convert` (or `-c`), following the output format (only `xlsx` is currently supported). For example, to convert `case5.m` into the `xlsx` format, run

```
andes run case5.m --convert xlsx
```

The output messages will look like

```
Parsing input file </Users/user/repos/andes/cases/matpower/case5.m>
CASE5 Power flow data for modified 5 bus, 5 gen case based on PJM 5-bus system
Input file case5.m parsed in 0.0033 second.
xlsx file written to </Users/user/repos/andes/cases/matpower/case5.xlsx>
```

(continues on next page)

(continued from previous page)

```
Converted file /Users/user/repos/andes/cases/matpower/case5.xlsx written in 0.
→5079 second.
-> Single process finished in 0.8765 second.
```

Note that `--convert` will only create sheets for existing models.

In case one wants to create template sheets to add models later, `--convert-all` can be used instead.

If one wants to add workbooks to an existing xlsx file, one can combine option `--add-book ADD_BOOK` (or `-b ADD_BOOK`), where `ADD_BOOK` can be a single model name or comma-separated model names (without any space). For example,

```
andes run kundur.raw -c -b Toggler
```

will convert file `kundur.raw` into an ANDES xlsx file (`kundur.xlsx`) and add a template workbook for *Toggler*.

**Warning:** With `--add-book`, the xlsx file will be overwritten. Any **empty or non-existent models** will be REMOVED.

## PSS/E inputs

To work with PSS/E input files (`.raw` and `.dyr`), one need to provide the raw file through `casefile` and pass the `dyr` file through `--addfile`. For example, in `andes/cases/kundur`, one can run the power flow using

```
andes run kundur.raw
```

and run a no-disturbance time-domain simulation using

```
andes run kundur.raw --addfile kundur_full.dyr -r tds
```

**Note:** If one wants to modify the parameters of models that are supported by both PSS/E and ANDES, one can directly edit those dynamic parameters in the `.raw` and `.dyr` files to maintain interoperability with other tools.

To create add a disturbance, there are two options. The recommended option is to convert the PSS/E data into an ANDES xlsx file, edit it and run (see the previous subsection).

An alternative is to edit the `.dyr` file with a plain-text editor (such as Notepad) and append lines customized for ANDES models. This is for advanced users after referring to `andes/io/psse-dyr.yaml`, at the end of which one can find the format of *Toggler*:

```
# === Custom Models ===
Toggler:
```

(continues on next page)

(continued from previous page)

```
inputs:
  - model
  - dev
  - t
```

To define two Toggler in the `.dyr` file, one can append lines to the end of the file using, for example,

```
Line  'Toggler'  Line_2  1 /
Line  'Toggler'  Line_2  1.1 /
```

which is separated by spaces and ended with a slash. The second parameter is fixed to the model name quoted by a pair of single quotation marks, and the others correspond to the fields defined in the above `inputs``. Each entry is properly terminated with a forward slash.

## andes plot

`andes plot` is the command-line tool for plotting. It currently supports time-domain simulation data. Three positional arguments are required, and a dozen of optional arguments are supported.

positional arguments:

Argument	Description
filename	simulation output file name, which should end with <i>out</i> . File extension can be omitted.
x	the X-axis variable index, typically 0 for Time
y	Y-axis variable indices. Space-separated indices or a colon-separated range is accepted

For example, to plot the generator speed variable of synchronous generator 1 `omega GENROU 0` versus time, read the indices of the variable (2) and time (0), run

```
andes plot kundur_full_out.lst 0 2
```

In this command, `andes plot` is the plotting command for TDS output files. `kundur_full_out.lst` is list file name. `0` is the index of Time for the x-axis. `2` is the index of `omega GENROU 0`. Note that for the file name, either `kundur_full_out.lst` or `kundur_full_out.npy` works, as the program will automatically extract the file name.

The y-axis variable indices can also be specified in the Python range fashion. For example, `andes plot kundur_full_out.npy 0 2:21:6` will plot the variables at indices 2, 8, 14 and 20.

`andes plot` will attempt to render with  $\LaTeX$  if `dvipng` program is in the search path. Figures rendered by  $\LaTeX$  is considerably better in symbols quality but takes much longer time. In case  $\LaTeX$  is available but fails (frequently happens on Windows), the option `-d` can be used to disable  $\LaTeX$  rendering.

Other optional arguments are listed in the following.

**optional arguments:**

Argument	Description
optional arguments:	
-h, --help	show this help message and exit
--xmin LEFT	minimum value for X axis
--xmax RIGHT	maximum value for X axis
--ymax YMAX	maximum value for Y axis
--ymin YMIN	minimum value for Y axis
--find FIND	find variable indices that matches the given pattern
--xargs XARGS	find variable indices and return as a list of arguments usable with "  xargs andes plot"
--exclude EXCLUDE	pattern to exclude in find or xargs results
-x XLABEL, --xlabel XLABEL	x-axis label text
-y YLABEL, --ylabel YLABEL	y-axis label text
-s, --savefig	save figure. The default fault is <i>png</i> .
-format SAVE_FORMAT	format for savefig. Common formats such as png, pdf, jpg are supported
--dpi DPI	image resolution in dot per inch (DPI)
-g, --grid	grid on
--greyscale	greyscale on
-d, --no-latex	disable LaTeX formatting
-n, --no-show	do not show the plot window
--ytimes YTIMES	scale the y-axis values by YTIMES
-c, --to-csv	convert npy output to csv

**andes doc**

`andes doc` is a tool for quick lookup of model and routine documentation. It is intended as a quick way for documentation.

The basic usage of `andes doc` is to provide a model name or a routine name as the positional argument. For a model, it will print out model parameters, variables, and equations to the stdio. For a routine, it will print out fields in the Config file. If you are looking for full documentation, visit [andes.readthedocs.io](https://andes.readthedocs.io).

For example, to check the parameters for model `Toggler`, run

```
$ andes doc Toggler
Model <Toggler> in Group <TimedEvent>

    Time-based connectivity status toggler.

Parameters
```

(continues on next page)

(continued from previous page)

Name	Description	Default	Unit	Type	Properties
u	connection status	1	bool	NumParam	
name	device name			DataParam	
model	Model or Group of the device			DataParam	mandatory
	to control				
dev	idx of the device to control			IdxParam	mandatory
t	switch time for connection	-1		TimerParam	mandatory
	status				

To list all supported models, run

```
$ andes doc -l
```

Supported Groups and Models

Group	Models
ACLine	Line
ACTopology	Bus
Collection	Area
DCLink	Ground, R, L, C, RCp, RCs, RLs, RLCs, RLCp
DCTopology	Node
Exciter	EXDC2
Experimental	PI2
FreqMeasurement	BusFreq, BusROCOF
StaticACDC	VSCShunt
StaticGen	PV, Slack
StaticLoad	PQ
StaticShunt	Shunt
SynGen	GENCLS, GENROU
TimedEvent	Toggler, Fault
TurbineGov	TG2, TGOV1

To view the Config fields for a routine, run

```
$ andes doc TDS
```

Config Fields in [TDS]

Option	Value	Info	Acceptable values
sparselib	klu	linear sparse solver name	('klu', 'umfpack')
tol	0.000	convergence tolerance	float
t0	0	simulation starting time	>=0
tf	20	simulation ending time	>t0
fixt	0	use fixed step size (1) or variable	(0, 1)
		(0)	

(continues on next page)

(continued from previous page)

shrinkt	1	shrink step size for fixed method if	(0, 1)
		not converged	
tstep	0.010	the initial step step size	float
max_iter	15	maximum number of iterations	>=10

## andes misc

`andes misc` contains miscellaneous functions, such as configuration and output cleaning.

## Configuration

ANDES uses a configuration file to set runtime configs for the system routines, and models. `andes misc --save-config` saves all configs to a file. By default, it saves to `~/.andes/andes.conf` file, where `~` is the path to your home directory.

With `andes misc --edit-config`, you can edit ANDES configuration handy. The command will automatically save the configuration to the default location if not exist. The shorter version `--edit` can be used instead as Python matches it with `--edit-config`.

You can pass an editor name to `--edit`, such as `--edit vim`. If the editor name is not provided, it will use the following defaults: - Microsoft Windows: `notepad`. - GNU/Linux: the `$EDITOR` environment variable, or `vim` if not exist.

For macOS users, the default is `vim`. If not familiar with `vim`, you can use `nano` with `--edit nano` or `TextEdit` with `--edit "open -a TextEdit"`.

## Cleanup

`andes misc -C, --clean`

Option to remove any generated files. Removes files with any of the following suffix: `_out.txt` (power flow report), `_out.npy` (time domain data), `_out.lst` (time domain variable list), and `_eig.txt` (eigenvalue report).

## 1.2.2 Interactive Usage

This section is a tutorial for using ANDES in an interactive environment. All interactive shells are supported, including Python shell, IPython, Jupyter Notebook and Jupyter Lab. The examples below uses Jupyter Notebook.

## Jupyter Notebook

Jupyter notebook is a convenient tool to run Python code and present results. Jupyter notebook can be installed with

```
conda install jupyter notebook
```

After the installation, change directory to the folder where you wish to store notebooks, then start the notebook with

```
jupyter notebook
```

A browser window should open automatically with the notebook browser loaded. To create a new notebook, use the "New" button near the upper-right corner.

---

**Note:** Code lines following `>>>` are Python code. Python code should be typed into a Python shell, IPython, or Jupyter Notebook, not a Anaconda Prompt or command-line shell.

---

## Import

Like other Python libraries, ANDES needs to be imported into an interactive Python environment.

```
>>> import andes
>>> andes.config_logger()
```

## Verbosity

If you are debugging ANDES, you can enable debug messages with

```
>>> andes.config_logger(stream_level=10)
```

The `stream_level` uses the same verbosity levels as for the command-line. If not explicitly enabled, the default level 20 (INFO) will apply.

To set a new logging level for the current session, call `config_logger` with the desired new levels.

## Making a System

Before running studies, a "System" object needs to be created to hold the system data. The System object can be created by passing the path to the case file to the entry-point function. For example, to run the file `kundur_full.xlsx` in the same directory as the notebook, use

```
>>> ss = andes.run('kundur_full.xlsx')
```

This function will parse the input file, run the power flow, and return the system as an object. Outputs will look like

```
Parsing input file </Users/user/notebooks/kundur/kundur_full.xlsx>
Input file kundur_full.xlsx parsed in 0.4172 second.
-> Power flow calculation with Newton Raphson method:
0: |F(x)| = 14.9283
1: |F(x)| = 3.60859
2: |F(x)| = 0.170093
3: |F(x)| = 0.00203827
4: |F(x)| = 3.76414e-07
Converged in 5 iterations in 0.0222 second.
Report saved to </Users/user/notebooks/kundur_full_out.txt> in 0.0015 second.
-> Single process finished in 0.4677 second.
```

In this example, `ss` is an instance of `andes.System`. It contains member attributes for models, routines, and numerical DAE.

Naming convention for the `System` attributes are as follows

- Model attributes share the same name as class names. For example, `ss.Bus` is the `Bus` instance.
- Routine attributes share the same name as class names. For example, `ss.PFlow` and `ss.TDS` are the routine instances.
- The numerical DAE instance is in lower case `ss.dae`.

To work with PSS/E inputs, refer to notebook [Example 2](#).

## Passing options

`andes.run()` can accept options that are available to the command-line `andes run`. Options need to be passed as keyword arguments to `andes.run()` in addition to the positional argument for the test case. For example, setting `no_output` to `True` will disable all file outputs. When scripting, one can do

```
>>> ss = andes.run('kundur_full.xlsx', no_output=True)
```

which is equivalent to the following shell command:

```
andes run kundur_full.xlsx --no-output
```

Please note that the dash between `no` and `output` needs to be replaced with an underscore for scripting. This is the convention in Python's argument parser.

Another example is to specify a folder for output files. By default, outputs will be saved to the folder where Python is run (or where the notebook is run). In case you need to organize outputs, a path prefix can be passed to `andes.run()` through `output_path`:

```
>>> ss = andes.run('kundur_full.xlsx', output_path='outputs/')
```

which will put outputs into folder `outputs` relative to the current path. You can also supply an absolute path to `output_path`.

The next example is to specify the simulation time for a time-domain simulation. There are multiple ways to implement it (see *Examples*), and one way is to pass the end time (in sec) through argument `tf` and set the routine to `tds`:

```
>>> ss = andes.run('kundur_full.xlsx', routine='tds', tf=5)
```

which will set the simulation time to 5 seconds.

---

**Note:** While `andes run` accepts single-letter alias for the option, such as `andes run -n` for `andes run --no-output`, `andes.run()` can only work with the full option name (with hyphen replaced by underscore)

---

## Inspecting Parameter

### DataFrame

Parameters for the loaded system can be easily inspected in Jupyter Notebook using Pandas.

Input parameters for each model instance is returned by the `as_df()` function. For example, to view the input parameters for Bus, use

```
>>> ss.Bus.as_df()
```

A table will be printed with the columns being each parameter and the rows being Bus instances. Parameter in the table is the same as the input file without per-unit conversion.

Parameters have been converted to per unit values under system base. To view the per unit values, use the `as_df(vin=True)` method. For example, to view the system-base per unit value of GENROU, use

```
>>> ss.GENROU.as_df(vin=True)
```

### Dict

In case you need the parameters in dict, use `as_dict()`. Values returned by `as_dict()` are system-base per unit values. To retrieve the input data, use `as_dict(vin=True)`.

For example, to retrieve the original input data of GENROU's, use

```
>>> ss.GENROU.as_dict(vin=True)
```

## Running Studies

Three routines are currently supported: PFlow, TDS and EIG. Each routine provides a `run()` method to execute. The System instance contains member attributes having the same names. For example, to run the time-domain simulation for `ss`, use

```
>>> ss.TDS.run()
```

## Checking Exit Code

`andes.System` contains field `exit_code` for checking if error occurred in run time. A normal completion without error should always have `exit_code == 0`. One should read output messages carefully and check the exit code, which is particularly useful for batch simulations.

Error may occur in any phase - data parsing, power flow, or simulation. To diagnose, split the simulation steps and check the outputs from each one.

## Plotting TDS Results

TDS comes with a plotting utility for interactive usage. After running the simulation, a `plotter` attributed will be created for TDS. To use the plotter, provide the attribute instance of the variable to plot. For example, to plot all the generator speed, use

```
>>> ss.TDS.plotter.plot(ss.GENROU.omega)
```

---

**Note:** If you see the error

AttributeError: 'NoneType' object has no attribute 'plot'

You will need to manually load plotter with

```
>>> ss.TDS.load_plotter()
```

---

Optional indices is accepted to choose the specific elements to plot. It can be passed as a tuple to the `a` argument

```
>>> ss.TDS.plotter.plot(ss.GENROU.omega, a=(0, ))
```

In the above example, the speed of the "zero-th" generator will be plotted.

## Scaling

A lambda function can be passed to argument `ycalc` to scale the values. This is useful to convert a per-unit variable to nominal. For example, to plot generator speed in Hertz, use

```
>>> ss.TDS.plotter.plot(ss.GENROU.omega, a=(0, ),
                        ycalc=lambda x: 60*x,
                        )
```

## Formatting

A few formatting arguments are supported:

- `grid = True` to turn on grid display
- `greyscale = True` to switch to greyscale
- `ylabel` takes a string for the y-axis label

## Extracting Data

One can extract data from ANDES for custom plotting. Variable names can be extracted from the following fields of `ss.dae`:

Un-formatted names (non-LaTeX):

- `x_name`: state variable names
- `y_name`: algebraic variable names
- `xy_name`: state variable names followed by algebraic ones

LaTeX-formatted names:

- `x_tex_name`: state variable names
- `y_tex_name`: algebraic variable names
- `xy_tex_name`: state variable names followed by algebraic ones

These lists only contain the variable names used in the current analysis routine. If you only ran power flow, `ss.dae.y_name` will only contain the power flow algebraic variables, and `ss.dae.x_name` will likely be empty. After initializing time-domain simulation, these lists will be extended to include all variables used by TDS.

In case you want to extract the discontinuous flags from TDS, you can set `store_z` to 1 in the config file under section [TDS]. When enabled, discontinuous flag names will be populated at

- `ss.dae.z_name`: discontinuous flag names
- `ss.dae.z_tex_name`: LaTeX-formatted discontinuous flag names

If not enabled, both lists will be empty.

## Power flow solutions

The full power flow solutions are stored at `ss.dae.xy` after running power flow (and before initializing dynamic models). You can extract values from `ss.dae.xy`, which corresponds to the names in `ss.dae.xy_name` or `ss.dae.xy_tex_name`.

If you want to extract variables from a particular model, for example, bus voltages, you can directly access the `v` field of that variable

```
>>> import numpy as np
>>> voltages = np.array(ss.Bus.v.v)
```

which stores a **copy** of the bus voltage values. Note that the first `v` is the voltage variable of `Bus`, and the second `v` stands for *value*. It is important to make a copy by using `np.array()` to avoid accidental changes to the solutions.

If you want to extract bus voltage phase angles, do

```
>>> angle = np.array(ss.Bus.a.v)
```

where `a` is the field name for voltage angle.

To find out names of variables in a model, use command `andes doc` or refer to [Model references](#).

## Time-domain data

Time-domain simulation data will be ready when simulation completes. It is stored in `ss.dae.ts`, which has the following fields:

- `txyz`: a two-dimensional array. The first column is time stamps, and the following are variables. Each row contains all variables for that time step.
- `t`: all time stamps.
- `x`: all state variables (one column per variable).
- `y`: all algebraic variables (one column per variable).
- `z`: all discontinuous flags (if enabled, one column per flag).

If you want the output in pandas DataFrame, call

```
ss.dae.ts.unpack(df=True)
```

Dataframes are stored in the following fields of `ss.dae.ts`:

- `df`: dataframe for states and algebraic variables
- `df_z`: dataframe for discontinuous flags (if enabled)

For both dataframes, time is the index column, and each column correspond to one variable.

## Pretty Print of Equations

Each ANDES models offers pretty print of  $\text{L}^{\text{A}}\text{T}_{\text{E}}\text{X}$ -formatted equations in the jupyter notebook environment.

To use this feature, symbolic equations need to be generated in the current session using

```
import andes
ss = andes.System()
ss.prepare()
```

Or, more concisely, one can do

```
import andes
ss = andes.prepare()
```

This process may take a few minutes to complete. To save time, you can selectively generate it only for interested models. For example, to generate for the classical generator model GENCLS, do

```
import andes
ss = andes.System()
ss.GENROU.prepare()
```

Once done, equations can be viewed by accessing `ss.<ModelName>.syms.<PrintName>`, where `<ModelName>` is the model name, and `<PrintName>` is the equation or Jacobian name.

---

**Note:** Pretty print only works for the particular `System` instance whose `prepare()` method is called. In the above example, pretty print only works for `ss` after calling `prepare()`.

---

Supported equation names include the following:

- `xy`: variables in the order of *State*, *ExtState*, *Algeb* and *ExtAlgeb*
- `f`: the **right-hand side of** differential equations  $T\dot{\mathbf{x}} = \mathbf{f}$
- `g`: implicit algebraic equations  $0 = \mathbf{g}$
- `df`: derivatives of `f` over all variables `xy`
- `dg`: derivatives of `g` over all variables `xy`
- `s`: the value equations for *ConstService*

For example, to print the algebraic equations of model GENCLS, one can use `ss.GENCLS.syms.g`.

## Finding Help

### General help

To find help on a Python class, method, or function, use the built-in `help()` function. For example, to check how the `get` method of `GENROU` should be called, do

```
help(ss.GENROU.get)
```

In Jupyter notebook, this can be simplified into `?ss.GENROU.get` or `ss.GENROU.get?`.

### Model docs

Model docs can be shown by printing the return of `doc()`. For example, to check the docs of `GENCLS`, do

```
print(ss.GENCLS.doc())
```

It is the same as calling `andes doc GENCLS` from the command line.

## 1.2.3 I/O Formats

### Input Formats

ANDES currently supports the following input formats:

- ANDES Excel (.xlsx)
- PSS/E RAW (.raw) and DYR (.dyr)
- MATPOWER (.m)

### ANDES xlsx Format

The ANDES xlsx format is a newly introduced format since v0.8.0. This format uses Microsoft Excel for conveniently viewing and editing model parameters. You can use [LibreOffice](#) or [WPS Office](#) alternatively to Microsoft Excel.

### xlsx Format Definition

The ANDES xlsx format contains multiple workbooks (tabs at the bottom). Each workbook contains the parameters of all instances of the model, whose name is the workbook name. The first row in a worksheet is used for the names of parameters available to the model. Starting from the second row, each row corresponds to an instance with the parameters in the corresponding columns. An example of the Bus workbook is shown in the following.

	A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P	Q
1	uid	idx	u	name	Vn	vmax	vmin	v0	a0	xcoord	ycoord	area	zone	owner			
2	0	1	1	1	20	1.1	0.9	1	0.570255	0	0	1	1	1			
3	1	2	1	2	20	1.1	0.9	0.99761	0.368746	0	0	1	1	1			
4	2	3	1	12	20	1.1	0.9	0.96263	0.185317	0	0	2	1	1			
5	3	4	1	11	20	1.1	0.9	0.81691	0.462359	0	0	2	1	1			
6	4	5	1	101	230	1.1	0.9	0.97928	0.480203	0	0	1	1	1			
7	5	6	1	102	230	1.1	0.9	0.95796	0.283887	0	0	1	1	1			
8	6	7	1	3	230	1.1	0.9	0.9362	0.126901	0	0	1	1	1			
9	7	8	1	13	230	1.1	0.9	0.87904	-0.08059	0	0	2	1	1			
10	8	9	1	112	230	1.1	0.9	0.89054	0.093618	0	0	2	1	1			
11	9	10	1	111	230	1.1	0.9	0.82958	0.336601	0	0	2	1	1			
12																	
13																	
14																	
15																	
16																	
17																	
18																	
19																	
20																	
21																	

A few columns are used across all models, including uid, idx, name and u.

- uid is an internally generated unique instance index. This column can be left empty if the xlsx file is being manually created. Exporting the xlsx file with `--convert` will automatically assign the uid.
- idx is the unique instance index for referencing. An unique idx should be provided explicitly for each instance. Accepted types for idx include numbers and strings without spaces.
- name is the instance name.
- u is the connectivity status of the instance. Accepted values are 0 and 1. Unexpected behaviors may occur if other numerical values are assigned.

As mentioned above, idx is the unique index for an instance to be referenced. For example, a PQ instance can reference a Bus instance so that the PQ is connected to the Bus. This is done through providing the idx of the desired bus as the bus parameter of the PQ.

	A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P	Q
1	uid	idx	u	name	bus	Vn	p0	q0	vmax	vmin	owner						
2	0	PQ_0	1		7	230	11.59	-0.735	1.1	0.9	1						
3	1	PQ_1	1		8	230	15.75	-0.899	1.1	0.9	1						
4																	
5																	
6																	
7																	
8																	
9																	
10																	
11																	
12																	
13																	
14																	
15																	
16																	
17																	
18																	
19																	
20																	
21																	

In the example PQ workbook shown above, there are two PQ instances on buses with `idx` being 7 and 8, respectively.

## Convert to xlsx

Please refer to the `--convert` command for converting a recognized file to xlsx. See Format Converter in the CLI tutorial.

## Data Consistency

Input data needs to have consistent types for `idx`. Both string and numerical types are allowed for `idx`, but the original type and the referencing type must be the same. Suppose we have a bus and a connected PQ. The Bus device may use 1 or '1' as its `idx`, as long as the PQ device uses the same value for its `bus` parameter.

The ANDES xlsx reader will try to convert data into numerical types when possible. This is especially relevant when the input `idx` is string literal of numbers, the exported file will have them converted to numbers. The conversion does not affect the consistency of data.

## Parameter Check

The following parameter checks are applied after converting input values to array:

- Any NaN values will raise a `ValueError`
- Any `inf` will be replaced with  $10^8$ , and `-inf` will be replaced with  $-10^8$ .

## 1.2.4 Per Unit System

The bases for AC system are

- $S_b^{ac}$ : three-phase power in MVA. By default,  $S_b^{ac} = 100 \text{ MVA}$  (set by `System.config.mva`).
- $V_b^{ac}$ : phase-to-phase voltage in kV.
- $I_b^{ac}$ : current base  $I_b^{ac} = \frac{S_b^{ac}}{\sqrt{3}V_b^{ac}}$

The bases for DC system are

- $S_b^{dc}$ : power in MVA. It is assumed to be the same as  $S_b^{ac}$ .
- $V_b^{dc}$ : voltage in kV.

Some device parameters are given as per unit values under the device base power and voltage (if applicable). For example, the Line model `andes.models.line.Line` has parameters `r`, `x` and `b` as per unit values in the device bases `Sn`, `Vn1`, and `Vn2`. It is up to the user to check data consistency. For example, line voltage bases are typically the same as bus nominal values. If the `r`, `x` and `b` are meant to be per unit values under the system base, each Line device should use an `Sn` equal to the system base `mva`.

Parameters in device base will have a property value in the Model References page. For example, `Line.r` has a property `z`, which means it is a per unit impedance in the device base. To find out all applicable properties, refer to the "Other Parameters" section of [andes.core.param.NumParam](#).

After setting up the system, these parameters will be converted to per units in the bases of system base MVA and bus nominal voltages. The parameter values in the system base will be stored to the `v` attribute of the `NumParam`. The original inputs in the device base will be moved to the `vin` attribute. For example, after setting up the system, `Line.x.v` is the line reactances in per unit under system base.

Values in the `v` attribute is what get utilized in computation. Writing new values directly to `vin` will not affect the values in `v` afterwards. To alter parameters after setting up, refer to example notebook 2.

## 1.2.5 Cheatsheet

A cheatsheet is available for quick lookup of supported commands.

View the PDF version at

<https://www.cheatography.com/cuihantao/cheat-sheets/andes-for-power-system-simulation/pdf/>

## 1.2.6 Make Documentation

The documentation you are viewing can be made locally in a variety of formats. To make HTML documentation, change directory to `docs`, and do

```
make html
```

After a minute, HTML documentation will be saved to `docs/build/html` with the index page being `index.html`.

A list of supported formats is as follows. Note that some format require additional compiler or library

html	to make standalone HTML files
dirhtml	to make HTML files named index.html <b>in</b> directories
singlehtml	to make a single large HTML file
pickle	to make pickle files
json	to make JSON files
htmlhelp	to make HTML files <b>and</b> an HTML help project
qthelp	to make HTML files <b>and</b> a qthelp project
devhelp	to make HTML files <b>and</b> a Devhelp project
epub	to make an epub
latex	to make LaTeX files, you can <b>set</b> PAPER=a4 <b>or</b> PAPER=letter
latexpdf	to make LaTeX <b>and</b> PDF files (default pdflatex)
latexpdfja	to make LaTeX files <b>and</b> run them through platex/dvipdfmx
text	to make text files
man	to make manual pages
texinfo	to make Texinfo files
info	to make Texinfo files <b>and</b> run them through makeinfo
gettext	to make PO message catalogs
changes	to make an overview of <b>all</b> changed/added/deprecated items
xml	to make Docutils-native XML files
pseudoxml	to make pseudoxml-XML files <b>for</b> display purposes
linkcheck	to check <b>all</b> external links <b>for</b> integrity
doctest	to run <b>all</b> doctests embedded <b>in</b> the documentation ( <b>if</b> enabled)
coverage	to run coverage check of the documentation ( <b>if</b> enabled)

## 1.3 Test Cases

### 1.3.1 Directory

ANDES comes with several test cases in the `andes/cases/` folder. Currently, the Kundur's 2-area system, IEEE 14-bus system, NPCC 140-bus system, and the WECC 179-bus system has been verified against DSATools TSAT.

The test case library will continue to build as more models get implemented.

A tree view of the test directory is as follows.

```

### 1.3.2 MATPOWER Cases

MATPOWER cases has been tested in ANDES for power flow calculation. All following cases are calculated with the provided initial values using the full Newton-Raphson iterative approach.

Note:

The 70K and the USA synthetic systems have difficulties to converge using the provided initial values. One can solve the case in MATPOWER and save it as a new case for ANDES. For example, the SyntheticUSA case can be converted in MATLAB with

```
mpc = runpf(case_SyntheticUSA)
savecase('USA.m', mpc)
```

And then solve it with ANDES from command line:

```
andes run USA.m
```

The output should look like

```
-> Power flow calculation
Sparse solver: KLU
Solution method: NR method
Power flow initialized.
0: \|F(x)\| = 140.5782767
1: \|F(x)\| = 29.61673314
2: \|F(x)\| = 4.161452394
3: \|F(x)\| = 0.2337870537
4: \|F(x)\| = 0.001149488448
5: \|F(x)\| = 3.646516689e-08
Converged in 6 iterations in 1.6082 seconds.
```

### 1.3.3 Performance

The numerical library used for sparse matrix factorization is KLU. In addition, Jacobians are updated in place `kvxopt.spmatrix.ipadd`. Computations are performed on WSL2 Ubuntu 20.04 with AMD Ryzen 9 5950X, 64 GB 3200 MHz DDR4, running ANDES 1.5.3, KVXOPT 1.2.7.1, NumPy 1.20.3, and numba 0.54.1. NumPy and KVXOPT use OpenBLAS 0.3.18. Numba is enabled, and the generated code are pre-compiled. Network connectivity checking is turned off. Time to read numba cache (~0.3s) is not counted.

The computation time may vary depending on operating system and hardware. All the cases are original in MATPOWER 7.0. Cases not listed below will not solve with ANDES 1.5.3.

## 1.4 Parsers

### 1.4.1 PSS/E Dyr Parser

ANDES supporting parsing PSS/E dynamic files in the format of .dyr. Support new dynamic models can be added by editing the input and output conversion definition file in `andes/io/psse-dyr.yaml`, which is in the standard YAML format. To add support for a new dynamic model, it is recommended to start with an existing model of similar functionality.

Consider a GENCLS entry in a dyr file. The entry looks like

```
1 'GENCLS' 1    13.0000  0.000000 /
```

where the fields are in the order of bus index, model name, generator index on the bus, inertia (H) and damping coefficient (D).

The input-output conversion definition for GENCLS is as follows

```
GENCLS:
  destination: GENCLS
  inputs:
    - BUS
    - ID
    - H
    - D
  find:
    gen:
      StaticGen:
        bus: BUS
        subidx: ID
  get:
    u:
      StaticGen:
        src: u
        idx: gen
    Sn:
      StaticGen:
        src: Sn
        idx: gen
    Vn:
```

(continues on next page)

(continued from previous page)

```

    Bus:
        src: Vn
        idx: BUS
    ra:
        StaticGen:
            src: ra
            idx: gen
    xs:
        StaticGen:
            src: xs
            idx: gen
    outputs:
        u: u
        bus: BUS
        gen: gen
        Sn: Sn
        Vn: Vn
        D: D
        M: "GENCLS.H; lambda x: 2 * x"
        ra: ra
        xd1: xs

```

It begins with a base-level definition of the model name to be parsed from the dyr file, namely, GENCLS. Five directives can be defined for each model: **destination**, **inputs**, **outputs**, **find** and **get**. Note that **find** and **get** are optional, but the other three are mandatory.

- **destination** is ANDES model to which the original PSS/E model will be converted. In this case, the ANDES model have the same name GENCLS.
- **inputs** is a list of the parameter names for the PSS/E data. Arbitrary names can be used, but it is recommended to use the same notation following the PSS/E manual.
- **outputs** is a dictionary where the keys are the ANDES model parameter and the values are the input parameter or lambda functions that processes the inputs (see notes below).
- **find** is a dictionary with the keys being the temporary parameter name to store the **idx** of external devices and the values being the criteria to locate the devices. In the example above, GENCLS will try to find the **idx** of **StaticGen** with **bus == BUS** and the **subidx == ID**, where **BUS** and **ID** are from the dyr file.
- **get** is a dictionary with each key being a temporary parameter name for storing an external parameter and each value being the criteria to find the external parameter. In the example above, a temporary parameter **u** is the **u** parameter of **StaticGen** whose **idx == gen**. Note that **gen** is the **idx** of **StaticGen** retrieved in the above **find** section.

For the **inputs** section, one will need to skip the model name because for any model, the second field is always the model name. That is why for GENCLS below, we only list four input parameters.

```
1 'GENCLS' 1      13.0000  0.000000 /
```

For the outputs section, the order can be arbitrary, but it is recommended to follow the input order as much as possible for maintainability. In particular, the right-hand-side of the outputs can be either an input parameter name or an anonymous expression that processes the input parameters. For the example of GENCLS, since ANDES internally uses the parameter of  $M = 2H$ , the input  $H$  needs to be multiplied by 2. It is done by the following

```
M: "GENCLS.H; lambda x: 2 * x"
```

where the left-hand-side is the output parameter name (destination ANDES model parameter name), and the right-hand-side is arguments and the lambda function separated by semi-colon, all in a pair of double quotation marks. Multiple arguments are accepted and should be separated by comma. Arguments can come from the same model or another model. In the case of the same model, the model name can be neglected, namely, by writing `M: "H; lambda x: 2 * x"`.

## 1.5 Config references

### 1.5.1 System

Option	Value	Info	Accepted values
freq	60	base frequency [Hz]	float
mva	100	system base MVA	float
ipadd	1	use spmatrix.ipadd if available	(0, 1)
seed	None	seed (or None) for random number generator	int or None
diag_eps	0.000	small value for Jacobian diagonals	
warn_limits	1	warn variables initialized at limits	(0, 1)
warn_abnormal	1	warn initialization out of normal values	(0, 1)
dime_enabled	0		
dime_name	andes		
dime_address	ipc:///tmp/dime2		
numba	0	use numba for JIT compilation	(0, 1)
numba_parallel	10	enable parallel for numba.jit	(0, 1)
numba_nopython	0	nopython mode for numba	(0, 1)
yapf_pycode	0	format generated code with yapf	(0, 1)
np_divide	warn	treatment for division by zero	{'ignore', 'log', 'call', 'print', 'warn', 'raise'}
np_invalid	warn	treatment for invalid floating-point ops.	{'ignore', 'log', 'call', 'print', 'warn', 'raise'}
pickle_path	/home/docs/.andes/callpickle	pickled models should be (un)pickled to/from	

### 1.5.2 PFlow

Option	Value	Info	Accepted values
sparselib	klu	linear sparse solver name	('klu', 'umfpack', 'spsolve', 'cupy')
linsolve	0	solve symbolic factorization each step (enable when KLU segfaults)	(0, 1)
tol	0.000	convergence tolerance	float
max_iter	25	max. number of iterations	>=10
method	NR	calculation method	('NR', 'dishonest')
check_conn	1	check connectivity before power flow	(0, 1)
n_factorize	4	first N iterations to factorize Jacobian in dishonest method	>0
report	1	write output report	(0, 1)
degree	0	use degree in report	(0, 1)
init_tds	0	initialize TDS after PFlow	(0, 1)

### 1.5.3 TDS

Option	Value	Info	Accepted values
sparselib	klu	linear sparse solver name	('klu', 'umfpack', 'spsolve', 'cupy')
linsolve	0	solve symbolic factorization each step (enable when KLU segfaults)	(0, 1)
method	trapezoid	DAE solution method	('trapezoid', 'backeuler')
tol	0.000	convergence tolerance	float
t0	0	simulation starting time	$\geq 0$
tf	20	simulation ending time	$> t_0$
fixt	1	use fixed step size (1) or variable (0)	(0, 1)
shrinkt	1	shrink step size for fixed method if not converged	(0, 1)
honest	0	honest Newton method that updates Jac at each step	(0, 1)
tstep	0.033	integration step size	float
max_iter	15	maximum number of iterations	$\geq 10$
re-fresh_event	0	refresh events at each step	(0, 1)
test_init	1	test if initialization passes	(0, 1)
check_conn	1	re-check connectivity after event	(0, 1)
g_scale	1	scale algebraic residuals with time step size	positive
reset_tiny	1	reset tiny residuals to zero to avoid chattering	(0, 1)
qrt	0	quasi-real-time stepping	(0, 1)
kqrt	1	quasi-real-time scaling factor; kqrt > 1 means slowing down	positive
store_z	0	store limiter status in TDS output	(0, 1)
store_f	0	store RHS of diff. equations	(0, 1)
store_h	0	store RHS of external diff. equations	(0, 1)
store_i	0	store RHS of external algeb. equations	(0, 1)
no_tqdm	0	disable tqdm progressbar and outputs	(0, 1)

### 1.5.4 EIG

Option	Value	Info	Accepted values
sparselib	klu	linear sparse solver name	('klu', 'umfpack', 'spsolve', 'cupy')
lin-solve	0	solve symbolic factorization each step (enable when KLU segfaults)	(0, 1)
plot	0	show plot after computation	(0, 1)
tol	0.000	numerical tolerance to treat eigenvalues as zeros	

## 1.6 Miscellaneous

### 1.6.1 Notes

#### Modeling Blocks

##### State Freeze

State freeze is used by converter controllers during fault transients to fix a variable at the pre-fault values. The concept of state freeze is applicable to both state or algebraic variables. For example, in the renewable energy electric control model (REECA), the proportional-integral controllers for reactive power error and voltage error are subject to state freeze when voltage dip is observed. The internal and output states should be frozen when the freeze signal turns one and freed when the signal turns back to zero.

Freezing a state variable can be easily implemented by multiplying the freeze signal with the right-hand side (RHS) of the differential equation:

$$T\dot{x} = (1 - z_f) \times f(x)$$

where  $f(x)$  is the original RHS of the differential equation, and  $z_f$  is the freeze signal. When  $z_f$  becomes zero the differential equation will evaluate to zero, making the increment zero.

Freezing an algebraic variable is more complicate to implement. One might consider a similar solution to freezing a differential variable by constructing a piecewise equation, for example,

$$0 = (1 - z_f) \times g(y)$$

where  $g(y)$  is the original RHS of the algebraic equation. One might also need to add a small value to the diagonals of `dae.gy` associated with the algebraic variable to avoid singularity. The rationale behind this implementation is to zero out the algebraic equation mismatch and thus stop incremental correction: in the frozen state, since  $z_f$  switches to zero, the algebraic increment should be forced to zero. This method, however, would not work when a dishonest Newton method is used.

If the Jacobian matrix is not updated after  $z_f$  switches to one, in the row associated with the equation, the derivatives will remain the same. For the algebraic equation of the PI controller given by

$$0 = (K_p u + x_i) - y$$

where  $K_p$  is the proportional gain,  $u$  is the input,  $x_i$  is the integrator output, and  $y$  is the PI controller output, the derivatives w.r.t  $u$ ,  $x_i$  and  $y$  are nonzero in the pre-frozen state. These derivative corrects  $y$  following the changes of  $u$  and  $x$ . Although  $x$  has been frozen, if the Jacobian is not rebuilt, correction will still be made due to the change of  $u$ . Since this equation is linear, only one iteration is needed to let  $y$  track the changes of  $u$ . For nonlinear algebraic variables, this approach will likely give wrong results, since the residual is pegged at zero.

To correctly freeze an algebraic variable, the freezing signal needs to be passed to an `EventFlag`, which will set an `custom_event` flag if any input changes. `EventFlag` is a `VarService` that will be evaluated at each iteration after discrete components and before equations.

## 1.6.2 Profiling Import

To speed up the command-line program, import profiling is used to breakdown the program loading time.

With tool `profimp`, `andes` can be profiled with `profimp "import andes" --html > andes_import.htm`. The report can be viewed in any web browser.

## 1.6.3 What won't not work

You might have heard that PyPy is faster than CPython due to a built-in JIT compiler. Before you spend an hour compiling the dependencies, here is the fact: PyPy won't work for speeding up ANDES.

PyPy is often much slower than CPython when using CPython extension modules (see the [PyPy\\_FAQ](#)). Unfortunately, NumPy is one of the highly optimized libraries that heavily use CPython extension modules.

# 1.7 Frequently Asked Questions

## 1.7.1 Program Startup

Q: Why do I get an "ImportError: DLL load failed" when running ANDES?

Platform: Windows, error message:

ImportError: DLL load failed: The specified module could not be found.

This usually happens when `andes` is not installed in a Conda environment but instead in a system-wide Python whose library path was not correctly set in environment variables.

The easiest fix is to install `andes` in a Conda environment.

## 1.7.2 General

Q: What is the Hybrid Symbolic-Numeric Framework in ANDES?

A: It is a modeling and simulation framework that uses symbolic computation for descriptive modeling and code generation for fast numerical simulation. The goal of the framework is to reduce the programming efforts associated with implementing complex models and automate the research workflow of modeling, simulation, and documentation.

The framework reduces the modeling efforts from two aspects: (1) allowing modeling by typing in equations, and (2) allowing modeling using modularized control blocks and discontinuous components. One only needs to describe the model using equations and blocks without having to write the numerical code to implement the computation. The framework automatically generate symbolic expressions, computes partial derivatives, and generates vectorized numerical code.

### 1.7.3 Modeling

#### Admittance matrix

Q: Where to find the line admittance matrix?

A: ANDES does not build line admittance matrix for computing line power injections. Instead, line power injections are computed as vectors on the two line terminal. This approach generalizes line as a power injection model.

Q: Without admittance matrix, how to switch out lines?

A: Lines can be switched out and in by using `Toggler`. See the example in `cases/kundur/kundur_full.xlsx`. One does not need to manually trigger a Jacobian matrix rebuild because `Toggler` automatically triggers it using the new connectivity status.

#### Reference of the existing model

Q: Is there any further reference of the existing model?

A: Most of them can be found online, such as ESIG and PowerWorld.

## 1.8 License

### 1.8.1 GNU Public License v3

Copyright 2015-2020 Hantao Cui.

ANDES is free software; you can redistribute it and/or modify it under the terms of the [GNU General Public License](#) as published by the Free Software Foundation; either version 3 of the License, or (at your option) any later version.

ANDES is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the [GNU General Public License](#) for more details.

## EXAMPLES

A collection of examples are presented to supplement the tutorial. The examples below are identical to the Jupyter Notebook in the `examples` folder of the repository [here](#). You can run the examples in a live Jupyter Notebook online using [Binder](#).

### 2.1 Simulate and Plot

#### 2.1.1 Import and Setting the Verbosity Level

We first import the `andes` library and the `get_case` function that for loading test cases shipped with ANDES.

```
import andes

from andes.utils.paths import get_case
```

We can configure the verbosity level for logging (output messages) by passing a verbosity level (10-DEBUG, 20-INFO, 30-WARNING, 40-ERROR, 50-CRITICAL) to the `stream_level` argument of `andes.main.config_logger()`. Verbose level 10 is useful for getting debug output.

The logging level can be altered (as of v1.4.3) by calling `config_logger` again with new `stream_level` and `file_level`.

```
andes.config_logger(stream_level=20)
```

Note that the above `andes.config_logger()` is a shorthand to `andes.main.config_logger()`.

If this step is omitted, the default INFO level (`stream_level=20`) will be used.

## 2.1.2 Run Time-Domain Simulation

### Run power flow by default

`get_case` takes a relative path to `ANDES_ROOT/andes/cases` and returns the full path, where `ANDES_ROOT` is the root folder of ANDES.

`andes.run` is the entrypoint function for loading files and running routines. It runs power flow by default and returns a `System` object.

Note: if `default_config=True`, the default config will be used. To use your own config, remove `default_config=True`.

See the tutorial for saving and editing ANDES config.

```
ss = andes.run(get_case('kundur/kundur_full.xlsx'), default_config=True)
```

```
Working directory: "/home/hacui/repos/andes/examples"
Loaded generated Python code in "/home/hacui/.andes/pycode".
Parsing input file "/home/hacui/repos/andes/andes/cases/kundur/kundur_full.xlsx".
→...
Input file parsed in 0.2025 seconds.
System internal structure set up in 0.0180 seconds.
-> System connectivity check results:
    No islanded bus detected.
    A total of 1 island(s) detected.
    Each island has a slack bus correctly defined and enabled.

-> Power flow calculation
    Sparse solver: KLU
    Solution method: NR method
Power flow initialized in 0.0024 seconds.
0: |F(x)| = 14.9282832
1: |F(x)| = 3.608627841
2: |F(x)| = 0.1701107882
3: |F(x)| = 0.002038626956
4: |F(x)| = 3.745103977e-07
Converged in 5 iterations in 0.0050 seconds.
Report saved to "kundur_full_out.txt" in 0.0006 seconds.
```

```
-> Single process finished in 0.3072 seconds.
```

## Run time-domain simulation

Run TDS by calling `TDS.run()` on the system. Note that the call must follow the power flow immediately.

The default simulation is for 20 seconds. To change it, change `config.tf` to the desired value.

```
ss.TDS.config.tf = 10 # simulate for 10 seconds
```

```
ss.TDS.run()
```

```
-> Time Domain Simulation Summary:
Sparse Solver: KLU
Simulation time: 0.0-10 s.
Fixed step size: h=33.33 ms. Shrink if not converged.
Initialization for dynamics completed in 0.0178 seconds.
Initialization was successful.
```

```
<Toggler 1>: Line.Line_8 status changed to 0 at t=2.0 sec.
100%|#####| 100/100 [00:00<00:00, 360.57%/s]
```

```
Simulation completed in 0.2777 seconds.
Outputs to "kundur_full_out.lst" and "kundur_full_out.npz".
Outputs written in 0.0078 seconds.
```

```
True
```

To check if all operations completed successfully, check `ss.exit_code`. `exit_code == 0` means that all operations were successful.

If not zero, `exit_code` indicates the number of errors caught. One will need to check output messages for errors.

```
ss.exit_code
```

```
0
```

### 2.1.3 Export and Plot Results

If you are using ANDES interactively from Jupyter Notebook or IPython, at the end of a time-domain simulation, a plotter object `ss.TDS.plt` will automatically be created.

To check if that has been created successfully (in case the detection of an interactive environment fails), check the type of `ss.TDS.plt`.

```
ss.TDS.plt
```

```
<andes.plot.TDSData at 0x7f9afbfe7430>
```

If `ss.TDS.plt` is `None`, it can be manually loaded with `ss.TDS.load_plotter()`. Otherwise, `load_plotter()` can be safely skipped.

```
ss.TDS.load_plotter()
```

## Exporting simulation data to csv

To export simulation results to a CSV file, one can use `ss.TDS.plt.export_csv()`, which takes an optional argument of the file name.

If not provided, a default file name will be assigned.

```
ss.TDS.plt.export_csv()
```

```
CSV data saved to "/home/hacui/repos/andes/examples/kundur_full_out.csv".
```

## Index-based Plotting

`plotter.plot()` is the entry point for plotting. It is the backend of the command-line `andes plot`.

Before plotting, open the `kundur_full_out.lst` to find the indices (first column) for the variables to plot.

For example, if we want to plot all generator speed, which is the `omega` variable of `GENROU`. By inspect, we found the indices as 5, 6, 7, 8.

Pass them in a tuple or a list to `ss.TDS.plt.plot`.

```
fig, ax = ss.TDS.plt.plot((5, 6, 7, 8))
```

`plot()` returns a figure object and an axis object.

### Find index by variable name

`plotter.find()` is a method for finding indices based on variable name.

The first argument is the pattern to find. An optional argument `exclude` is the pattern to exclude. Regular expression is supported for both.

```
ss.TDS.plt.find('omega')
```

```
([5, 6, 7, 8],
 ['omega GENROU 1', 'omega GENROU 2', 'omega GENROU 3', 'omega GENROU 4'])
```

```
fig, ax = ss.TDS.plotter.plot(ss.TDS.plotter.find('omega')[0])
```

### Plotting by variable

Looking up indices from the 1st file can be tedious.

Instead, one can pass a variable in a model to `ss.TDS.plt.plot`. For example, to plot `ss.GENROU.omega`, do

```
fig, ax = ss.TDS.plt.plot(ss.GENROU.omega)
```

To plot a subset of the variables, pass the 0-indexed selection indices in a tuple through argument `a` of `ss.TDS.plt.plot`. For example, to plot the 0-th and the 3-th GENROU.omega, do

```
fig, ax = ss.TDS.plt.plot(ss.GENROU.omega, a=(0, 3))
```

## Adding curves to an existing figure

Plotting curves into an existing figure allows easy comparison of results. It can be done by passing a figure and an axis object of `plot()`.

For example, to plot the speed of the second generator ( $a=1$ ) on the figure above, do

```
fig, ax = ss.TDS.plt.plot(ss.GENROU.omega, a=(1, ), fig=fig, ax=ax, linestyle=[
    ↪ '-.'])
fig
```

<Figure size 432x288 with 0 Axes>

## Y-axis label

```
fig, ax = ss.TDS.plotter.plot((5, 6, 7, 8), ylabel='Generator speed [p.u.]')
```

### Legend names (yheader)

```
fig, ax = ss.TDS.plotter.plot((5, 6, 7, 8), ylabel='Generator speed [p.u.]',
                              yheader=['Spd 1', 'Spd 2', 'Spd 3', 'Spd 4'])
```

Note that the number of elements passed to `yheader` should match the number of variables. `yheader` only

applies to new curves and cannot be used to modify existing legends.

## Scaling

A lambda function can be passed to `ycalc` to scale the value. To scale the frequency from per unit to 60 Hz nominal values, use

```
fig, ax = ss.TDS.plotter.plot((5, 6, 7, 8), ycalc=lambda x: 60 * x)
```

## Greyscale and Grid

```
fig, ax = ss.TDS.plotter.plot((5, 6, 7, 8),  
                               ycalc=lambda x: 60 * x,  
                               greyscale=True,  
                               grid=True)
```

### Save figure

Pass `savefig = True` to save the figure to a png file.

```
fig, ax = ss.TDS.plotter.plot((5, 6, 7, 8), savefig=True)
```

Figure saved to "kundur\_full\_out\_1.png".

### Additional arguments

`plotter.plot` takes addition arguments. To check additional arguments, please use help or refer to the source code.

```
help(ss.TDS.plotter.plot)
```

Help on method plot in module andes.plot:

```
plot(yidx, xidx=(0,), *, a=None, ytimes=None, ycalc=None, left=None, right=None,
↳ ymin=None, ymax=None, xlabel=None, ylabel=None, xheader=None, yheader=None,
↳ legend=None, grid=False, greyscale=False, latex=True, dpi=100, line_width=1.0,
↳ font_size=12, savefig=None, save_format=None, show=True, title=None,
↳ linestyle=None, use_bqplot=False, hline1=None, hline2=None, vline1=None,
↳ vline2=None, hline=None, vline=None, fig=None, ax=None, backend=None, set_
↳ xlim=True, set_ylim=True, autoscale=False, legend_bbox=None, legend_loc=None,
↳ legend_ncol=1, figsize=None, color=None, **kwargs) method of andes.plot.
```

↳ TDSData instance

Entry function for plotting.

This function retrieves the x and y values based on the ``xidx`` and ``yidx`` inputs, applies scaling functions ``ytimes`` and ``ycalc`` sequentially, and delegates the plotting to the backend.

Parameters

(continues on next page)

(continued from previous page)

```

-----
yidx : list or int
    The indices for the y-axis variables
xidx : tuple or int, optional
    The index for the x-axis variable
a : tuple or list, optional
    The 0-indexed sub-indices into `yidx` to plot.
ytimes : float, optional
    A scaling factor to apply to all y values.
left : float
    The starting value of the x axis
right : float
    The ending value of the x axis
ymin : float
    The minimum value of the y axis
ymax : float
    The maximum value of the y axis
ylabel : str
    Text label for the y axis
yheader : list
    A list containing the variable names for the y-axis variable
title : str
    Title string to be shown at the top
fig
    Existing figure object to draw the axis on.
ax
    Existing axis object to draw the lines on.

```

#### Other Parameters

```

-----
ycalc: callable, optional
    A callable to apply to all y values after scaling with `ytimes`.
xlabel : str
    Text label for the x axis
xheader : list
    A list containing the variable names for the x-axis variable
legend : bool
    True to show legend and False otherwise
legend_ncol : int
    Number of columns in legend
legend_bbox : tuple of two floats
    legend box to anchor
grid : bool
    True to show grid and False otherwise
latex : bool
    True to enable latex and False to disable

```

(continues on next page)

(continued from previous page)

```

greyscale : bool
    True to use greyscale, False otherwise
savefig : bool or str
    True to save to png figure file.
    str is treated as the output file name.
save_format : str
    File extension string (pdf, png or jpg) for the savefig format
dpi : int
    Dots per inch for screen print or save.
    `savefig` uses a minimum of 200 dpi
line_width : float
    Plot line width
font_size : float
    Text font size (labels and legends)
figsize : tuple
    Figure size passed when creating new figure
show : bool
    True to show the image
backend : str or None
    `bqplot` to use the bqplot backend in notebook.
    None for matplotlib.
hline1: float, optional
    Dashed horizontal line 1
hline2: float, optional
    Dashed horizontal line 2
vline1: float, optional
    Dashed horizontal line 1
vline2: float, optional
    Dashed vertical line 2
hline: float or Iterable
    y-axis location of horizontal line(s)
vline: float or Iterable
    x-axis location of vertical line(s)

```

Returns

-----

(fig, ax)

Figure and axis handles for matplotlib backend.

fig

Figure object for bqplot backend.

## 2.1.4 Cleanup

```
! andes misc -C
```

```

      _          _          | Version 1.5.12.post16.dev0+g316e4bdf

```

## 2.2 Working with Data

This example shows how to work with the data of a loaded test system, including parameters and variables.

```
import andes
from andes.utils.paths import get_case

andes.config_logger()
```

To show all the rows and columns, change the pandas configuration with

```
import pandas as pd

pd.options.display.max_columns = None
pd.options.display.max_rows = None
```

Let's load the Kundur's system.

### 2.2.1 Load System from an ANDES XLSX File

The ANDES xlsx file is the best supported format. Other formats can be converted to the xlsx format.

See the link below for more about format conversion. <https://github.com/cuihantao/andes/blob/master/README.md#format-converter>

As previously shown, test cases can be loaded with `andes.run()`:

```
ss = andes.run(get_case('kundur/kundur_full.xlsx'),
               default_config=True) # one can remove `default_config=True` to
↳ use custom config file
```

```
Working directory: "/home/hacui/repos/andes/examples"

Report saved to "kundur_full_out.txt" in 0.0006 seconds.
```

```
-> Single process finished in 0.4505 seconds.
```

Alternatively, one can load a test case *without setting up* using `andes.load(..., setup=False)`. Note that `setup=False` option. It is useful to apply parameter changes to an existing test case.

```
ss = andes.load(get_case('kundur/kundur_full.xlsx'),
                default_config=True,
                setup=False)
```

```
Working directory: "/home/hacui/repos/andes/examples"
Reloaded generated Python code of module "pycode".
Parsing input file "/home/hacui/repos/andes/andes/cases/kundur/kundur_full.xlsx".
↪...
Input file parsed in 0.0380 seconds.
```

For example, we can toggle the connectivity status `u` of `Line_3` to `0` using

```
ss.Line.alter('u', 'Line_3', 0)
```

When done, remember to set up the system before running calculation routines:

```
ss.setup()

ss.PFlow.run()
```

```
System internal structure set up in 0.0336 seconds.
-> System connectivity check results:
    No islanded bus detected.
    A total of 1 island(s) detected.
    Each island has a slack bus correctly defined and enabled.

```

After setting up the system, adding or removing devices are not yet allowed.

## 2.2.2 Load System from PSS/E RAW and DYP Files

ANDES supports loading systems from PSS/E RAW and DYP files.

The PSS/E v32 raw format is best supported.

Note that this feature is experimental. We try out best to support this format, but the compatibility is not guaranteed.

```
raw_path = get_case('kundur/kundur.raw')
dyp_path = get_case('kundur/kundur_full.dyp')
```

The raw file is passed to the positional argument, whereas the dyp file is passed to `addfile`.

```
ss = andes.run(raw_path, addfile=dyr_path, default_config=True)
```

```
Working directory: "/home/hacui/repos/andes/examples"
Reloaded generated Python code of module "pycode".
Parsing input file "/home/hacui/repos/andes/andes/cases/kundur/kundur.raw"...
  MODIFIED KUNDUR'S TWO-AREA TEST SYSTEM, DISTRIBUTED WITH ANDES

```

## Attributes for storing values

Parameters are stored as attributes of the model. For example, `ss.GENROU.M`, the machine starting time constant (2H), is stored in `ss.GENROU.M`.

```
ss.GENROU.M
```

```
NumParam: GENROU.M, v=[117.    117.    111.15 111.15], vin=[13.    13.    12.35 12.
↳ 35]
```

It is an instance of `NumParam`, which contains fields `v` for the values after converting to system-base per unit values.

```
ss.GENROU.M.v
```

```
array([117.    , 117.    , 111.15, 111.15])
```

And field `vin` is for the original input data.

```
ss.GENROU.M.vin
```

```
array([13. , 13. , 12.35, 12.35])
```

### Tabulated view

ANDES provides tabulated **view** of model parameters by using DataFrame. Each model object has an attribute called `cache` for caching the parameter dataframes.

The original parameters from the input file are stored in `cache.df_in` of the model object. For GENROU, do

```
ss.GENROU.cache.df_in
```

	idx	u	name	bus	gen	coi	coi2	Sn	Vn	fn	D	\
uid												
0	GENROU_1	1.0	GENROU_1	1	1	None	None	900.0	20.0	60.0	0.0	
1	GENROU_2	1.0	GENROU_2	2	2	None	None	900.0	20.0	60.0	0.0	
2	GENROU_3	1.0	GENROU_3	3	3	None	None	900.0	20.0	60.0	0.0	
3	GENROU_4	1.0	GENROU_4	4	4	None	None	900.0	20.0	60.0	0.0	

	M	ra	xl	xd1	kp	kw	S10	S12	gammap	gammaq	xd	xq	\
uid													
0	13.00	0.0	0.06	0.3	0.0	0.0	0.0	0.0	1.0	1.0	1.8	1.7	
1	13.00	0.0	0.06	0.3	0.0	0.0	0.0	0.0	1.0	1.0	1.8	1.7	
2	12.35	0.0	0.06	0.3	0.0	0.0	0.0	0.0	1.0	1.0	1.8	1.7	
3	12.35	0.0	0.06	0.3	0.0	0.0	0.0	0.0	1.0	1.0	1.8	1.7	

	xd2	xq1	xq2	Td10	Td20	Tq10	Tq20
uid							
0	0.25	0.55	0.25	8.0	0.03	0.4	0.05
1	0.25	0.55	0.25	8.0	0.03	0.4	0.05
2	0.25	0.55	0.25	8.0	0.03	0.4	0.05
3	0.25	0.55	0.25	8.0	0.03	0.4	0.05

Parameters will be **converted** to per-unit in the system base after loading. This process have been done if `andes.run` is used for loading the data file.

To inspect the converted parameters, check the `cache.df` parameter.

```
ss.GENROU.cache.df
```

	idx	u	name	bus	gen	coi	coi2	Sn	Vn	fn	D	\

2	111.15	0.0	0.006667	0.033333	0.0	0.0	0.0	0.0	1.0	1.0	0.2
3	111.15	0.0	0.006667	0.033333	0.0	0.0	0.0	0.0	1.0	1.0	0.2
	xq	xd2	xq1	xq2	Td10	Td20	Tq10	Tq20			
uid											
0	0.188889	0.027778	0.061111	0.027778	8.0	0.03	0.4	0.05			
1	0.188889	0.027778	0.061111	0.027778	8.0	0.03	0.4	0.05			
2	0.188889	0.027778	0.061111	0.027778	8.0	0.03	0.4	0.05			
3	0.188889	0.027778	0.061111	0.027778	8.0	0.03	0.4	0.05			

One will notice the converted parameters such as M, xl, and all other impedances.

**It is very important to notice that `cache.df` and `cache.df_in` are both views. Altering data in these views will NOT alter the underlying parameter values.**

To alter values, see the example below.

## Altering parameters

Parameters can be altered by calling the `alter` method on a model instance.

We first look up the original value through `get`.

Either `v` or `vin` can be passed to argument `attr` to retrieve the converted or the original data. Here we are retrieving the original input data. If `attr` is not provided, `get` returns the value after per-unit conversion, which is the value used for calculation, by default.

```
ss.GENROU.get("M", "GENROU_1", attr='vin')
```

```
13.0
```

To change the M of GENROU\_1 to 10, do

```
ss.GENROU.alter("M", "GENROU_1", 10)
```

The value set through `alter` is always the data before per-unit conversion - just like it should have been in an input file. ANDES will perform the conversion and set `vin` and `v` correctly.

Parameters altered through `Model.alter()` can be saved as a new system using

```
andes.io.xlsx.write(ss, 'new_system.xlsx', overwrite=True)
```

```
xlsx file written to "new_system.xlsx"
```

```
True
```

## Refreshing the view

As mentioned, `cache.df` and `cache.df_in` are *cached* views and will not be automatically updated for inspection.

This is generally not an issue if one performs the simulation after altering data. However, if one needs to inspect the data again, `cache.refresh()` needs to be called manually.

```
ss.GENROU.cache.refresh()
```

```
ss.GENROU.cache.df_in
```

	idx	u	name	bus	gen	coi	coi2	Sn	Vn	fn	D	\
uid												
0	GENROU_1	1.0	GENROU_1	1	1	None	None	900.0	20.0	60.0	0.0	
1	GENROU_2	1.0	GENROU_2	2	2	None	None	900.0	20.0	60.0	0.0	
2	GENROU_3	1.0	GENROU_3	3	3	None	None	900.0	20.0	60.0	0.0	
3	GENROU_4	1.0	GENROU_4	4	4	None	None	900.0	20.0	60.0	0.0	

	M	ra	xl	xd1	kp	kw	S10	S12	gammap	gammaq	xd	xq	\
uid													
0	10.00	0.0	0.06	0.3	0.0	0.0	0.0	0.0	1.0	1.0	1.8	1.7	
1	13.00	0.0	0.06	0.3	0.0	0.0	0.0	0.0	1.0	1.0	1.8	1.7	
2	12.35	0.0	0.06	0.3	0.0	0.0	0.0	0.0	1.0	1.0	1.8	1.7	
3	12.35	0.0	0.06	0.3	0.0	0.0	0.0	0.0	1.0	1.0	1.8	1.7	

	xd2	xq1	xq2	Td10	Td20	Tq10	Tq20
uid							
0	0.25	0.55	0.25	8.0	0.03	0.4	0.05
1	0.25	0.55	0.25	8.0	0.03	0.4	0.05
2	0.25	0.55	0.25	8.0	0.03	0.4	0.05
3	0.25	0.55	0.25	8.0	0.03	0.4	0.05

Alternatively, one can call the `as_df()` function to build a new dataframe *without overwriting* the cache:

```
ss.GENROU.as_df()
```

	idx	u	name	bus	gen	coi	coi2	Sn	Vn	fn	D	\
uid												
0	GENROU_1	1.0	GENROU_1	1	1	None	None	900.0	20.0	60.0	0.0	
1	GENROU_2	1.0	GENROU_2	2	2	None	None	900.0	20.0	60.0	0.0	

(continues on next page)

(continued from previous page)

2	GENROU_3	1.0	GENROU_3	3	3	None	None	900.0	20.0	60.0	0.0
3	GENROU_4	1.0	GENROU_4	4	4	None	None	900.0	20.0	60.0	0.0
	M	ra	xl	xd1	kp	kw	S10	S12	gammap	gammaq	xd \
uid

3	0.188889	0.027778	0.061111	0.027778	8.0	0.03	0.4	0.05			

## 2.2.3 Variables

### Snapshots

One might also want to check the variable values in a similar way to that for a parameter. Certainly, a variable has a `v` attribute which stores values.

**It is important to note that `v` only holds the values at the last program state.** Such program state could be the solution of power flow, the initialization of time-domain simulation, or the end of a simulation disturbances.

Since we have only ran power flow for `ss`, `ss.Bus.v.v` are the voltage magnitude solutions, where the first `v` is for "voltage", and the second `v` is the first `v`'s value attribute.

```
ss.Bus.v.v
```

```
array([1.          , 1.          , 1.          , 1.          , 0.98337472,
        0.96908585, 0.9562181 , 0.95400018, 0.96856366, 0.98377143])
```

Variables hold more than values. They have an attribute `a` for the addresses indexing into the corresponding type of array.

There are two system-level arrays, `ss.dae.x` and `ss.dae.y` for the right-hand-side of the differential and algebraic equations, respectively.

```
type(ss.Bus.v)
```

```
andes.core.var.Algeb
```

`ss.Bus.v` is an algebraic variable, thus `ss.Bus.v.a` holds the indices into `ss.dae.g`.

```
ss.dae.y[ss.Bus.v.a]
```

```
array([1.          , 1.          , 1.          , 1.          , 0.98337472,
       0.96908585, 0.9562181 , 0.95400018, 0.96856366, 0.98377143])
```

We can see that these two values are the same.

## Time series

After a time-domain simulation, the time series of the variables can be retrieved through `ss.dae.ts`. Let's first run a simulation.

```
ss.TDS.run()
```

```
-> Time Domain Simulation Summary:
Sparse Solver: KLU
Simulation time: 0.0-20.0 s.
Fixed step size: h=33.33 ms. Shrink if not converged.
Initialization for dynamics completed in 0.0293 seconds.
Initialization was successful.
```

```
<Toggler Toggler_1>: Line.Line_8 status changed to 0 at t=2.0 sec.
100%|-----| 100/100 [00:00<00:00, 139.47%/s]
```

```
Simulation completed in 0.7172 seconds.
Outputs to "kundur_out.lst" and "kundur_out.npz".
Outputs written in 0.0179 seconds.
```

```
True
```

```
ss.dae.ts
```

```
<andes.variables.dae.DAETimeSeries at 0x7f2108b35ac0>
```

`ss.dae.ts` has four commonly used attributes: `t` for time stamps, `xy` for variables (differential and then algebraic), `z` for discontinuous states, and `df` for the dataframe of all.

- Each point in `ss.dae.ts.t` correspond to a row in `ss.dae.ts.xy`.
- Each column in `ss.dae.ts.xy` correspond to a variable, whose name can be located in `ss.dae.xy_name`, for all timestamps.
- `z` is not stored by default unless one enables it before simulation by setting `ss.TDS.config.store_z = 1`.

- `df` is not built by default but can be manually triggered after simulation by calling `ss.dae.ts.unpack(df=True)`

The following are some statistics of the shapes of arrays:

```
ss.dae.ts.t.shape
```

```
(603,)
```

```
ss.dae.ts.xy.shape # x-axis is for time stamps, and y-axis is for variables
```

```
(603, 204)
```

```
len(ss.dae.xy_name)
```

```
204
```

## Extracting Variable Data

Let's extract the data for rotor speed (variable `omega`) of GENROU generators. The first step to extract variable data is to determine the type of the variable: differential or algebraic. One can print the variable to see the type:

```
ss.GENROU.omega
```

```
State: GENROU.omega, a=[4 5 6 7], v=[1.0016599 1.00166701 1.00182666 1.
↪00184462], e=[-0.00238804 -0.00360342 0.00131428 0.00161908]
```

The output shows that `omega` is a state (differential variable), which should be looked up in `ss.dae.x`. For algebraic variables such as `ss.Bus.v`, they should be looked up in `ss.dae.y`.

Therefore, all `omega` variables can be extracted as follows:

```
omega = ss.dae.ts.x[:, ss.GENROU.omega.a]
```

where the `:` in the first axis will access such data for all time stamps, the `a` field of `ss.GENROU.omega` stores the addresses into `ss.dae.x`.

To access all bus voltages (algebraic variable `v`) of the generators, one can use:

```
ss.dae.ts.y[:, ss.GENROU.v.a]
```

```
array([[1.          , 1.          , 1.          , 1.          ],
       [1.          , 1.          , 1.          , 1.          ],
       [1.          , 1.          , 1.          , 1.          ],
       ...,

```

(continues on next page)

(continued from previous page)

```
[1.00241882, 1.00149857, 0.99525458, 1.00006109],
[1.00250567, 1.00159638, 0.99514609, 0.99997064],
[1.00259407, 1.00169544, 0.99503479, 0.99987801]]])
```

These data correspond to the timestamps stored in `ss.dae.ts.t`. One can process such data as necessary. To show verify the extracted data, we plot them with `ss.TDS.plt.plot_data`.

```
ss.TDS.plt.plot_data(ss.dae.ts.t, omega )
```

(<Figure size 600x400 with 1 Axes>, <AxesSubplot:>)

## 2.2.4 Cleanup

```
!andes misc -C
```

```

_          _          | Version 1.5.8.post16.dev0+g00a5f9be

```

```
!rm new_system.xlsx
```

## 2.3 Inspecting Models

First of all, import `andes` and configure the logger.  
If logger is not configured, information will not be shown correctly.

```
import andes

andes.main.config_logger(stream_level=30)
```

### 2.3.1 Inspect Model Equations

Create an empty `andes.System` object and call `prepare()` to generate the equations.  
This operation may take a moment.

```
ss = andes.System()
ss.prepare(nomp=True)  # disable multiprocessing
```

```
Generating code for COI (83/83).2/83)..
```

#### List all models

```
print(ss.supported_models())
```

Supported Groups and Models

### 2.3.2 Check model documentation

To check the documentation for the model, print the return of `doc()` for the model instance.

For example, the documentation for GENCLS can be printed with

```
print(ss.GENCLS.doc())
```

Model <GENCLS> in Group <SynGen>

Classical generator model.

Parameters

Name	Description	Default	Unit	Properties
idx	unique device idx			
u	connection status	1	bool	
name	device name			
bus	interface bus id			mandatory
gen	static generator index			mandatory
coi	center of inertia index			

(continues on next page)

(continued from previous page)

coi2	center of inertia index			
Sn	Power rating	100	MVA	
Vn	AC voltage rating	110		
fn	rated frequency	60		
D	Damping coefficient	0		power
M	machine start up time (2H)	6		non_zero,power
ra	armature resistance	0		z
xl	leakage reactance	0		z
xd1	d-axis transient reactance	0.302		z
kp	active power feedback gain	0		
kw	speed feedback gain	0		
S10	first saturation factor	0		
S12	second saturation factor	1		
gammap	P ratio of linked static gen	1		
gammaq	Q ratio of linked static gen	1		
subidx	Generator idx in plant; only used by PSS/E data	0		

## Variables (States + Algebraics)

Name	Type	Description	Unit	Properties
delta	State	rotor angle	rad	v_str
omega	State	rotor speed	pu (Hz)	v_str
Id	Algeb	d-axis current		v_str
Iq	Algeb	q-axis current		v_str
vd	Algeb	d-axis voltage		v_str
vq	Algeb	q-axis voltage		v_str
tm	Algeb	mechanical torque		v_str
te	Algeb	electric torque		v_str
vf	Algeb	excitation voltage	pu	v_str
XadIfd	Algeb	d-axis armature excitation current	p.u (kV)	v_str
Pe	Algeb	active power injection		v_str
Qe	Algeb	reactive power injection		v_str
psid	Algeb	d-axis flux		v_str
psiq	Algeb	q-axis flux		v_str
a	ExtAlgeb	Bus voltage phase angle		
v	ExtAlgeb	Bus voltage magnitude		

## Variable Initialization Equations

Name	Type	Initial Value
delta	State	delta0
omega	State	u

(continues on next page)

(continued from previous page)

Id	Algeb	$u * Id0$
Iq	Algeb	$u * Iq0$
vd	Algeb	$u * vd0$
vq	Algeb	$u * vq0$
tm	Algeb	$tm0$
te	Algeb	$u * tm0$
vf	Algeb	$u * vf0$
XadIfd	Algeb	$u * vf0$
Pe	Algeb	$u * (vd0 * Id0 + vq0 * Iq0)$
Qe	Algeb	$u * (vq0 * Id0 - vd0 * Iq0)$
psid	Algeb	$u * psid0$
psiq	Algeb	$u * psiq0$
a	ExtAlgeb	
v	ExtAlgeb	

## Differential Equations

Name	Type	RHS of Equation " $T \ x' = f(x, y)$ "	T (LHS)
-----+-----+-----+-----			
delta	State	$u * (2 * \pi * fn) * (\omega - 1)$	
omega	State	$u * (tm - te - D * (\omega - 1))$	M

## Algebraic Equations

Name	Type	RHS of Equation " $0 = g(x, y)$ "
-----+-----+-----		
Id	Algeb	$+ xq * Id - vf + psid$
Iq	Algeb	$+ xq * Iq + psiq$
vd	Algeb	$u * v * \sin(\delta - a) - vd$
vq	Algeb	$u * v * \cos(\delta - a) - vq$
tm	Algeb	$tm0 - tm$
te	Algeb	$u * (psid * Iq - psiq * Id) - te$
vf	Algeb	$u * vf0 - vf$
XadIfd	Algeb	$u * vf0 - XadIfd$
Pe	Algeb	$u * (vd * Id + vq * Iq) - Pe$
Qe	Algeb	$u * (vq * Id - vd * Iq) - Qe$
psid	Algeb	$u * (ra * Iq + vq) - psid$
psiq	Algeb	$u * (ra * Id + vd) + psiq$
a	ExtAlgeb	$-u * (vd * Id + vq * Iq)$
v	ExtAlgeb	$-u * (vq * Id - vd * Iq)$

## Services

Name	Equation	Type
-----+-----+-----		
p0	$p0s * \text{gammap}$	ConstService

(continues on next page)

(continued from previous page)

q0	q0s * gammaq	ConstService
_V	v * exp(1j * a)	ConstService
_S	p0 - 1j * q0	ConstService
_I	_S / conj(_V)	ConstService
_E	_V + _I * (ra + 1j * xq)	ConstService
_deltac	log(_E / abs(_E))	ConstService
delta0	u * im(_deltac)	ConstService
vdq	u * (_V * exp(1j * 0.5 * pi - _deltac))	ConstService
Idq	u * (_I * exp(1j * 0.5 * pi - _deltac))	ConstService
Id0	re(Idq)	ConstService
Iq0	im(Idq)	ConstService
vd0	re(vdq)	ConstService
vq0	im(vdq)	ConstService
tm0	u * ((vq0 + ra * Iq0) * Iq0 + (vd0 + ra * Id0) *   Id0)	ConstService
psid0	u * (ra * Iq0) + vq0	ConstService
psiq0	-u * (ra * Id0) - vd0	ConstService
vf0	(vq0 + ra * Iq0) + xq * Id0	ConstService

## Config Fields in [GENCLS]

Option	Value	Info	Acceptable values
allow_adjust	1	allow adjusting upper or lower limits	(0, 1)
adjust_lower	0	adjust lower limit	(0, 1)
adjust_upper	1	adjust upper limit	(0, 1)
vf_lower	1	lower limit for vf warning	
vf_upper	5	upper limit for vf warning	

## Pretty print of variables

All symbols are stored in the attributes of `Model.syms`. For example,

```
ss.GENCLS.syms.xy
```

$$\begin{bmatrix} \delta \\ \omega \\ I_d \\ I_q \\ V_d \\ V_q \\ \tau_m \\ \tau_e \\ v_f \\ X_{ad}I_{fd} \\ P_e \\ Q_e \\ \psi_d \\ \psi_q \\ \theta \\ V \end{bmatrix}$$

Differential variables comes before algebraic variables.

```
ss.GENCLS.states
```

```
OrderedDict([('delta', State: GENCLS.delta, []),
             ('omega', State: GENCLS.omega, [])])
```

```
ss.GENCLS.algebs
```

```
OrderedDict([('Id', Algeb: GENCLS.Id, []),
             ('Iq', Algeb: GENCLS.Iq, []),
             ('vd', Algeb: GENCLS.vd, []),
             ('vq', Algeb: GENCLS.vq, []),
             ('tm', Algeb: GENCLS.tm, []),
             ('te', Algeb: GENCLS.te, []),
             ('vf', Algeb: GENCLS.vf, []),
             ('XadIfd', Algeb: GENCLS.XadIfd, []),
             ('Pe', Algeb: GENCLS.Pe, []),
             ('Qe', Algeb: GENCLS.Qe, []),
             ('psid', Algeb: GENCLS.psid, []),
             ('psiq', Algeb: GENCLS.psiq, [])])
```

## Pretty print of equations

Formatted equations are stored in each model. The following attributes of `Model.syms` are available for equation printing.

- f: differential equations
- g: algebraic equations
- df: df/dxy
- dg: dg/dxy

```
ss.GENCLS.syms.f
```

$$\begin{bmatrix} 2\pi f u (\omega - 1) \\ u (-D (\omega - 1) - \tau_e + \tau_m) \end{bmatrix}$$

```
ss.GENCLS.syms.g
```

$$\begin{bmatrix} I_d x_q + \psi_d - v_f \\ I_q x_q + \psi_q \\ V u \sin(\delta - \theta) - V_d \\ V u \cos(\delta - \theta) - V_q \\ -\tau_m + \tau_{m0} \\ -\tau_e + u (-I_d \psi_q + I_q \psi_d) \\ u v_{f0} - v_f \\ -X_{ad} I_{fd} + u v_{f0} \\ -P_e + u (I_d V_d + I_q V_q) \\ -Q_e + u (I_d V_q - I_q V_d) \\ -\psi_d + u (I_q r_a + V_q) \\ \psi_q + u (I_d r_a + V_d) \\ -u (I_d V_d + I_q V_q) \\ -u (I_d V_q - I_q V_d) \end{bmatrix}$$

```
ss.GENCLS.syms.df
```

$$\begin{bmatrix} 0 & 2\pi f u & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -D u & 0 & 0 & 0 & 0 & u & -u & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

```
ss.GENCLS.syms.dg
```

$$\begin{bmatrix}
0 & 0 & xq & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & xq & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\
Vu \cos(\delta - \theta) & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -Vu \cos(\delta - \theta) \\
-Vu \sin(\delta - \theta) & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & Vu \sin(\delta - \theta) \\
0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & -\psi_{qu} & \psi_{du} & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & I_{qu} & -I_{du} & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & V_{du} & V_{qu} & I_{du} & I_{qu} & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\
0 & 0 & V_{qu} & -V_{du} & -I_{qu} & I_{du} & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & r_{au} & 0 & u & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 \\
0 & 0 & r_{au} & 0 & u & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & -V_{du} & -V_{qu} & -I_{du} & -I_{qu} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & -V_{qu} & V_{du} & I_{qu} & -I_{du} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}$$

### Pretty print of services

The list of services is in `services`.

```
ss.GENCLS.services
```

```
OrderedDict([('p0', ConstService: GENCLS.p0, v=[0.]),
             ('q0', ConstService: GENCLS.q0, v=[0.]),
             ('_V', ConstService: GENCLS._V, v=[0.]),
             ('_S', ConstService: GENCLS._S, v=[0.]),
             ('_I', ConstService: GENCLS._I, v=[0.]),
             ('_E', ConstService: GENCLS._E, v=[0.]),
             ('_deltac', ConstService: GENCLS._deltac, v=[0.]),
             ('delta0', ConstService: GENCLS.delta0, v=[0.]),
             ('vdq', ConstService: GENCLS.vdq, v=[0.]),
             ('Idq', ConstService: GENCLS.Idq, v=[0.]),
             ('Id0', ConstService: GENCLS.Id0, v=[0.]),
             ('Iq0', ConstService: GENCLS.Iq0, v=[0.]),
             ('vd0', ConstService: GENCLS.vd0, v=[0.]),
             ('vq0', ConstService: GENCLS.vq0, v=[0.]),
             ('tm0', ConstService: GENCLS.tm0, v=[0.]),
             ('psid0', ConstService: GENCLS.psid0, v=[0.]),
             ('psiq0', ConstService: GENCLS.psiq0, v=[0.]),
             ('vf0', ConstService: GENCLS.vf0, v=[0.])])
```

Service equations are in `Model.syms.s` For example, services of GENCLS is in

```
ss.GENCLS.syms.s
```

$$\begin{bmatrix} P_{0s}\gamma_P \\ Q_{0s}\gamma_Q \\ Ve^{i\theta} \\ P_0 - iQ_0 \\ \frac{S}{\text{conj}(V_c)} \\ I_c(r_a + ixq) + V_c \\ \log\left(\frac{E}{\text{abs}(E)}\right) \\ u \text{im}(\delta_c) \\ V_c u e^{-\delta_c + 0.5i\pi} \\ I_c u e^{-\delta_c + 0.5i\pi} \\ \text{re}(I_{dq}) \\ \text{im}(I_{dq}) \\ \text{re}(V_{dq}) \\ \text{im}(V_{dq}) \\ u(I_{d0}(I_{d0}r_a + V_{d0}) + I_{q0}(I_{q0}r_a + V_{q0})) \\ I_{q0}r_a u + V_{q0} \\ -I_{d0}r_a u - V_{d0} \\ I_{d0}xq + I_{q0}r_a + V_{q0} \end{bmatrix}$$

## 2.4 Eigenvalue Analysis

### 2.4.1 Run Eigenvalue Analysis

```
import andes
from andes.utils.paths import list_cases, get_case
```

```
case_path = get_case('kundur/kundur_full.xlsx')
```

Pass the routine name `EIG` or `eig` to `andes.run`.

```
ss = andes.run(case_path, routine='eig')
```

```
Working directory: "/home/hacui/repos/andes/examples"
Loaded config from file "/home/hacui/.andes/andes.rc"
Loaded generated Python code in "/home/hacui/.andes/pycode".
Parsing input file "/home/hacui/repos/andes/andes/cases/kundur/kundur_full.xlsx".
↪...
Input file parsed in 0.1963 seconds.
System internal structure set up in 0.0220 seconds.
-> System connectivity check results:
    No islanded bus detected.
    A total of 1 island(s) detected.
```

(continues on next page)

(continued from previous page)

Each island has a slack bus correctly defined and enabled.

```
-> Power flow calculation
    Sparse solver: KLU
    Solution method: NR method
Numba compilation initiated with caching.
Power flow initialized in 0.2135 seconds.
0: |F(x)| = 14.9282832
1: |F(x)| = 3.608627841
2: |F(x)| = 3.371691245
3: |F(x)| = 3.38335788
4: |F(x)| = 1.643469337
5: |F(x)| = 0.2341714002

"/home/hacui/repos/andes/examples/kundur_full_out.txt" removed.
"/home/hacui/repos/andes/examples/kundur_full_eig.txt" removed.
```

## 2.5 Using CLI from Notebook

This example notebook is a supplement to the ANDES tutorial. Make sure you have read the tutorial on using the CLI first.

A brief version can be found at <https://github.com/cuihantao/andes/blob/master/README.md#run-simulations>

### 2.5.1 The ! magic in iPython

This example shows how to use the ANDES CLI from Jupyter Notebook.

It is based on the iPython magic `!`. To run a command *from within* IPython or Jupyter, place a `!` immediately before the command.

Conversely, all commands demonstrated in this notebook can be used in a terminal/shell by removing the preceding `!` sign.

## 2.5.2 Set up on Windows

Windows users will need to install [MSYS2](#) to support most of the Linux shell commands.

To install MSYS2-base, uncomment the following line and run it:

```
# !conda install -c msys2 -n base --yes m2-base
```

## 2.5.3 Running Shell Commands

For example, to list the directory , use `!ls`. This is equivalent to executing `ls` from the terminal.

```
!ls
```

```
'10. load-frequency-control.ipynb'  '6. using-cli-from-notebook.ipynb'
'1. simulate_and_plot.ipynb'        '7. parallel-simulation.ipynb'
'2. inspect_data.ipynb'             '8. change-setpoints.ipynb'
'3. eigenvalue.ipynb'               '9. batch-processing.ipynb'
'4. inspect_models.ipynb'           demonstration
'5. profiling.ipynb'                verification
```

Likewise, to run `andes`, use `!andes`. Addition arguments can be passed as usual.

```
!andes
```

```

usage: andes [-h] [-v {1,10,20,30,40}] [--version]
           {run,plot,doc,misc,prepare,prep,selftest,st,demo} ...

positional arguments:
  {run,plot,doc,misc,prepare,prep,selftest,st,demo}
    [run] run simulation routine; [plot] plot results;
    [doc] quick documentation; [misc] misc. functions;
    [prepare] prepare the numerical code; [selftest] run
    self test; [demo] show demos.

optional arguments:
  -h, --help            show this help message and exit
  -v {1,10,20,30,40}, --verbose {1,10,20,30,40}
                        Verbosity level in 10-DEBUG, 20-INFO, 30-WARNING, or
                        40-ERROR.
  --version             show version info and exit
```

## 2.5.4 Run a simulation

Pass the path to the case file and other arguments to andes from the command line as follows.

```
!andes run ../andes/cases/kundur/kundur_full.xlsx -r tds
```

```

## PSS/E RAW and DYR Files

To run a simulation using PSS/E raw and dyr files, pass the dyr file to argument `--addfile`.

For example:

```
!andes run ../andes/cases/kundur/kundur.raw --addfile ../andes/cases/kundur/
↪kundur_full.dyr -r tds
```

```

## 2.5.6 Plot and save to file

We found a limitation of using `andes plot` from within Notebook/iPython. The figure won't be displayed correctly. The workaround is to save the image as a file and display it from the notebook.

Please let us know if you have better solutions.

```
!andes plot kundur_full_out.lst 0 5 6 --save
```

```
Figure saved to "kundur_full_out_1.png".  
Figure(640x480)
```

### 2.5.7 Display image

```
from IPython.display import Image  
Image("kundur_full_out_1.png")
```

### 2.5.8 Using xargs for index loop up

A convenient tool in Linux/macOS is `xargs`, which turns the standard output of one program into arguments for another.

`andes plot --xargs` accepts an input of search pattern for variable names and returns a list of arguments, including the matched indices, that can be understood by `andes plot`.

A convenient tool in Linux/macOS/Windows with MSYS2 is `xargs`, which turns the standard output of one program into arguments for another.

`andes plot --xargs` accepts an input of search pattern for variable names and returns a list of arguments, including the matched indices, that can be understood by `andes plot`.

## 2.5.9 Using xargs for index lookup

A convenient tool in Linux/macOS is `xargs`, which turns the standard output of one program into arguments for another.

`andes plot --xargs` accepts an input of search pattern for variable names and returns a list of arguments, including the matched indices, that can be understood by `andes plot`.

To illustrate, let's look at an example output of `andes plot --xargs`.

```
!andes plot kundur_full_out.lst --xargs "omega GENROU"
```

```
kundur_full_out.lst 0 5 6 7 8
```

The output consists of the `lst` file name, the default x-axis index `0`, and the indices for the found variables. The full output can be passed to `andes plot` without modification.

We use the following command to pass the arguments:

```
!andes plot kundur_full_out.lst --xargs "omega GENROU" | xargs andes plot
```

```
Figure(640x480)
```

where `|` is the pipe operator in shell for piping the standard output of the left-hand side to the right-hand side, `xargs` captures the pipe-in and appends it to `andes plot`.

The command is equivalent to manually running

```
!andes plot kundur_full_out.lst 5 6 7 8
```

```
Figure(640x480)
```

## 2.5.10 Cleanup

Remove the saved `png` image files.

```
!rm -v *.png
```

```
removed 'kundur_full_out_1.png'
```

```
!andes misc -C
```

```

## 2.6 Batch Processing - Generate Cases

This notebook demonstrates creating cases in batch and running them in parallel.

### 2.6.1 Create Cases in Batch

The approach to create cases in batch following this procedure:

- Load the base case from file
- For each desired case output:
  - Alter parameters to the desired value
  - Save each system to a new case file

```
import andes  
import numpy as np  
from andes.utils.paths import get_case  
  
andes.config_logger(stream_level=30) # brief logging
```

```
# create directory for output cases  
!rm -rf batch_cases  
!mkdir -p batch_cases
```

```
kundur = get_case('kundur/kundur_full.xlsx')  
ss = andes.load(kundur)
```

We demonstrate running the Kundur's system under different loading conditions.

Cases are created by modifying the `p0` of PQ with `idx == PQ_0`.

As always, input parameters can be inspected by accessing `Model.as_df(vin=True)`.

```
p0_base = ss.PQ.get('p0', "PQ_0")
```

Create 3 cases so that the load increases from `p0_base` to `1.2 * p0_base`.

```
N_CASES = 3 # Note: increase `N_CASES` as necessary

p0_values = np.linspace(p0_base, 1.2 * p0_base, N_CASES)
```

```
for value in p0_values:
    ss.PQ.alter('p0', 'PQ_0', value)
    file_name = f'batch_cases/kundur_p_{value:.2f}.xlsx'

    andes.io.dump(ss, 'xlsx', file_name, overwrite=True)
```

## 2.6.2 Parallel Simulation

Parallel simulation is easy with the command line tool.

Change directory to batch\_cases:

```
import os

# change the Python working directory
os.chdir('batch_cases')
```

```
!ls -la
```

```
total 56
drwxrwxr-x 2 hacui hacui  4096 Dec 14 14:51 .
drwxrwxr-x 6 hacui hacui  4096 Dec 14 14:51 ..
-rw-rw-r-- 1 hacui hacui 14640 Dec 14 14:51 kundur_p_11.59.xlsx
-rw-rw-r-- 1 hacui hacui 14641 Dec 14 14:51 kundur_p_12.75.xlsx
-rw-rw-r-- 1 hacui hacui 14640 Dec 14 14:51 kundur_p_13.91.xlsx
```

## Running from Command line

```
!andes run *.xlsx -r tds
```

```

```

## Number of CPUs

In some cases, you don't want the simulation to use up all resources.

ANDES allows to control the number of processes to run in parallel through `--ncpu NCPU`, where NCPU is the maximum number of processes (equivalent to the number of CPU cores) allowed.

```
!andes run *.xlsx -r tds --ncpu 4
```

```

```

## Running with APIs

Setting `pool = True` allows returning all system instances in a list.

This comes with a penalty in computation time but can be helpful if you want to extract data directly.

```
systems = andes.run('*.xlsx', routine='tds', pool=True, verbose=10)
```

Cases are processed in the following order:

```

"kundur_p_11.59.xlsx"
"kundur_p_12.75.xlsx"
"kundur_p_13.91.xlsx"

```

```
PQ.vcmp out of limits <vmin>
```

```

idx  | Flag | Input Value | Limit
-----+-----+-----+-----
PQ_1 | z1   | 0.888       | 0.900

```

```
0%|                                     | 0/100 [00:00<?, ?%/s]
```

```
PQ.vcmp out of limits <vmin>
```

idx	Flag	Input Value	Limit
PQ_1	z1	0.833	0.900

```
<Toggler 1>: Line.Line_8 status changed to 0 at t=2.0 sec.
<Toggler 1>: Line.Line_8 status changed to 0 at t=2.0 sec.
<Toggler 1>: Line.Line_8 status changed to 0 at t=2.0 sec.
100%|-----| 100/100 [00:00<00:00, 202.24%/s]
100%|-----| 100/100 [00:00<00:00, 189.78%/s]
100%|-----| 100/100 [00:00<00:00, 190.62%/s]

```

## Example plots

Plotting or data analyses can be carried out as usual.

```
ss = systems[0]
```

```
systems[0].TDS.plotter.plot(ss.GENROU.omega, latex=False)
```

```
(<Figure size 600x400 with 1 Axes>, <AxesSubplot:xlabel='Time [s]')>)
```

```
systems[2].TDS.plotter.plot(ss.GENROU.omega, latex=False)
```

```
(<Figure size 600x400 with 1 Axes>, <AxesSubplot:xlabel='Time [s]')>)
```

```
!andes misc -C
!rm -rf batch_cases
```

```

```

No output file found in the working directory.

## 2.7 Batch Processing - in Memory

This notebook shows examples for batch power flow and time-domain calculations. Readers are supposed to have read the previous examples, especially Example 7 for parallel simulations.

```
import andes
import numpy as np

from matplotlib import pyplot as plt
```

The following line sets verbosity level to WARNING to suppress some outputs. Comment it out to receive more outputs.

```
andes.main.config_logger(stream_level=30)
```

### 2.7.1 Batch Power Flow Calculation

Use the Kundur's system as the example. Suppose we want to calculate power flow for the same system structure but for different load levels.

```
kundur = andes.utils.get_case('kundur/kundur_full.xlsx')
```

```
ss = andes.run(kundur, no_output=True, default_config=True)
```

```
-> Single process finished in 0.3336 seconds.
```

There are two PQ loads in the Kundur's system with idxes of PQ\_0 and PQ\_1.

```
ss.PQ.as_df(vin=True)
```

	idx	u	name	bus	Vn	p0	q0	vmax	vmin	owner
uid										
0	PQ_0	1.0	None	7	230.0	11.59	-0.735	1.1	0.9	1
1	PQ_1	1.0	None	8	230.0	15.75	-0.899	1.1	0.9	1

If we have a range of active power for each load, such as

```
n_samples = 3 # Note: increase `n_samples` for higher data resolution

pq0_values = np.linspace(10, 12, n_samples)
pq1_values = np.linspace(12, 18, n_samples)
```

where there are 3 samples for PQ\_0.p0 between [10, 12] and 10 samples for PQ\_1.p0 between (12, 18).

We can use a for loop to set the load values and calculate power flow for each point.

Suppose we want to retrieve the voltage magnitude for each case, we use v\_results the voltage results. Results that are not saved will be discarded.

```
v_results = np.zeros((ss.Bus.n, n_samples ** 2))
idx = 0

for ii in pq0_values:
    for jj in pq1_values:

        ss.PQ.alter("p0", "PQ_0", ii)
        ss.PQ.alter("p0", "PQ_1", jj)

        ss.PFlow.run()
        v_results[:, idx] = ss.dae.y[ss.Bus.v.a]

        idx += 1
```

Let's plot the results.

```
lines = plt.plot(v_results)

xl = plt.xlabel('Bus Name')
yl = plt.ylabel('Voltage [p.u.]')

tk = plt.xticks(np.arange(ss.Bus.n), ss.Bus.name.v)
```

One should be aware that the for-loop based approach is single-threaded. It does not take advantage of multi-core processors.

If the total number of scenarios are huge, one should refer to Example 7 to save all scenarios to excel files and use multi-processing.

## 2.7.2 Batch Time-Domain Simulation

The next example shows how to run batch time-domain simulations for different events.

Suppose we want to create one scenario for each line trip event, which is actuated through Toggler. For the same system, we want to add Toggles for each line, run the simulation, and save results.

```
kundur = andes.utils.get_case('kundur/kundur_full.xlsx')
```

We use `andes.load()` with `setup=False` to load the test case.

**It is important to note that one must pass `setup=False` so that adding Toggles can be allowed.**

```
ss = andes.load(kundur, setup=False)
```

The `idxes` of all available lines to trip are in `ss.Line.idx.v`:

```
idxes = ss.Line.idx.v
```

```
ss.Toggler.as_df()
```

	idx	u	name	model	dev	t
uid						
0	1	1	Toggler_1	Line	Line_8	2

We use `ss.add()` to add two togglers for each line at 1 second and 1.1 seconds to simulate a line opening and closing. `ss.add()` takes a model name, "Toggler", as the positional argument, and a dictionary for the Toggler device parameters.

A note for this particular test case is that `kundur_full.xlsx` already comes with a Toggler with `idx==1`. To not to interfere with our scenarios, we need to disable it using `ss.Toggler.alter`.

After adding Toggler devices, we need to manually call `ss.setup()` to finish the data structure setup. Then, power flow and time-domain simulation can be performed.

We store the results in a dictionary where keys are the line names and values are the systems. Code is as follows.

```
results = dict()

for idx in idxes:
    ss = andes.load(kundur, setup=False)

    ss.add('Toggler', dict(model="Line", dev=idx, t=1.0))
    ss.add('Toggler', dict(model="Line", dev=idx, t=1.1))

    ss.setup() # no `ss.add()` calls are allowed after setup()
    ss.Toggler.alter('u', 1, 0.0) # disable the existing toggler with idx=1
    ↪(this is for the particular case)

    ss.PFlow.run()
    ss.TDS.config.tf = 5 # simulate for 5 seconds to save time
    ss.TDS.run()

    results[idx] = ss
```

```

100%|-----| 100/100 [00:00<00:00, 240.94%/s]

```

Not all cases will solve due to system instability. For the converged cases, one can export the data or plot results following Example 1.

```

for idx, ss in results.items():
    ss.TDS.plt.plot(ss.GENROU.omega, title=f'{idx} trip', latex=False, dpi=80)

```

```
!rm -rf batch_cases/
```

## 2.8 Changing Setpoints

This notebook shows an example of changing the generator setpoints in a time-domain simulation. Data in this example is trivial, but the example can be retrofitted for scenarios such as economic dispatch incorporation or reinforcement learning.

Steps are the following:

1. Initialize a system by running the power flow,
2. Set the first simulation stop time in `TDS.config.tf`,
3. Run the simulation,
4. Update the setpoints,
5. Set the new simulation stop time and repeat from 3 until the end.

## 2.8.1 Step 1: Case Setup

```
import andes
from andes.utils import get_case
```

```
kundur = get_case('kundur/kundur_full.xlsx')
```

```
ss = andes.run(kundur)
```

```
Working directory: "/home/hacui/repos/andes/examples"
Loaded generated Python code in "/home/hacui/.andes/pycode".
Parsing input file "/home/hacui/repos/andes/andes/cases/kundur/kundur_full.xlsx".
↪...
Input file parsed in 0.1974 seconds.
System internal structure set up in 0.0226 seconds.
-> System connectivity check results:
    No islanded bus detected.
    A total of 1 island(s) detected.
    Each island has a slack bus correctly defined and enabled.

-> Power flow calculation
    Sparse solver: KLU
    Solution method: NR method
Power flow initialized in 0.0019 seconds.
0: |F(x)| = 14.9282832
1: |F(x)| = 3.608627841
2: |F(x)| = 0.1701107882
3: |F(x)| = 0.002038626956
4: |F(x)| = 3.745103977e-07
Converged in 5 iterations in 0.0031 seconds.
Report saved to "kundur_full_out.txt" in 0.0006 seconds.
```

```
-> Single process finished in 0.3298 seconds.
```

```
# disable the Toggler in this case
ss.Toggler.alter('u', 1, 0)
```

## 2.8.2 Step 2: Set the First Stop Time

```
# simulate to t=1 sec

# specify the first stop in `ss.TDS.config.tf`
ss.TDS.config.tf = 1
```

## 2.8.3 Step 3: Run Simulation

```
ss.TDS.run()
```

```
-> Time Domain Simulation Summary:
Sparse Solver: KLU
Simulation time: 0.0-1 s.
Fixed step size: h=33.33 ms. Shrink if not converged.
Initialization for dynamics completed in 0.0212 seconds.
Initialization was successful.
```

```
100%|-----| 100/100 [00:00<00:00, 2688.31%/s]
```

```
Simulation completed in 0.0374 seconds.
Outputs to "kundur_full_out.lst" and "kundur_full_out.npz".
Outputs written in 0.0010 seconds.
```

```
True
```

## 2.8.4 Step 4. Apply the auxiliary power setpoints to TGOV1.paux0.v

First, let's check the equations of TGOV1. `ss.TGOV1.paux0` is associated with equation `0 = paux - paux0`, in which `paux` is added to the power input equation.

```
print(ss.TGOV1.doc())
```

```
Model <TGOV1> in Group <TurbineGov>
```

```
    TGOV1 turbine governor model.
```

```
    Implements the PSS/E TGOV1 model without deadband.
```

```
Parameters
```

```

```
ss.TGOV1.paux0.v
```

```
array([0., 0., 0., 0.])
```

```
# MUST use in-place assignments.
# Here, we increase the setpoint of the 0-th generator

# method 1: use in-place assignment again

ss.TGOV1.paux0.v[0] = 0.05

# method 2: use ``ss.TGOV1.alter()``

# ss.TGOV1.alter('paux0', 1, 0.05)
```

```
ss.TGOV1.paux0.v
```

```
array([0.05, 0., 0., 0.])
```

Continue to simulate to 2 seconds.

```
ss.TDS.config.tf = 2
```

```
ss.TDS.run()
```

```
100%|-----| 100.0/100 [00:00<00:00, 1360.42%/s]
```

```
Simulation completed in 0.0737 seconds.  
Outputs to "kundur_full_out.lst" and "kundur_full_out.npz".  
Outputs written in 0.0026 seconds.
```

```
True
```

```
ss.TDS.plotter.plot(ss.TGOV1.paux)
```

```
(<Figure size 600x400 with 1 Axes>, <AxesSubplot:xlabel='Time [s] '>)
```

```
ss.TDS.plotter.plot(ss.TGOV1.pout)
```

(<Figure size 600x400 with 1 Axes>, <AxesSubplot:xlabel='Time [s] '>)

```
ss.TDS.plotter.plot(ss.GENROU.omega)
```

(<Figure size 600x400 with 1 Axes>, <AxesSubplot:xlabel='Time [s] '>)

### 2.8.5 Step 5: Set Another New Setpoints and New Ending Time.

In this example, we clear the auxiliary power previously set to `TGOV1.paux0.v`

```
# method 1: use in-place assignment again
```

```
ss.TGOV1.paux0.v[0] = 0.
```

```
# method 2: use ``ss.TGOV1.alter()``
```

```
# ss.TGOV1.alter('paux0', 1, 0)
```

```
# set the new ending time to 10 sec.
```

```
ss.TDS.config.tf = 10
```

```
ss.TDS.run()
```

```
100%|-----| 100.0/100 [00:00<00:00, 286.76%/s]
```

```
Simulation completed in 0.3491 seconds.
```

```
Outputs to "kundur_full_out.lst" and "kundur_full_out.npz".
```

```
Outputs written in 0.0103 seconds.
```

```
True
```

```
ss.TDS.plotter.plot(ss.TGOV1.paux)
```

(<Figure size 600x400 with 1 Axes>, <AxesSubplot:xlabel='Time [s] '>)

```
ss.TDS.plotter.plot(ss.GENROU.omega)
```

(<Figure size 600x400 with 1 Axes>, <AxesSubplot:xlabel='Time [s] '>)

```
!andes misc -C
```

## 2.9 Load Frequency Control

This examples shows (1) how to trip a generator, and (2) how to drive frequency back by load shedding.

```
import andes
import numpy as np

andes.config_logger(stream_level=20)
```

### 2.9.1 Tripping a Generator in the IEEE 14-Bus System

```

# using the IEEE 14-bus model as an example.
# The example here contains a variety of models: generators, exciters, turbine,
↳ governors, and PSS
# To speed up, one can remove unneeded ones, e.g., PSS

ieee14_raw = andes.get_case("ieee14/ieee14.raw")
ieee14_dyr = andes.get_case("ieee14/ieee14.dyr")
```

```

# use `andes.load` to load the test system
# Need to set `setup=False` to be able to add new Toggles that turns off,
↳ generators.

ss = andes.load(ieee14_raw, addfile=ieee14_dyr, setup=False)
```

```

Working directory: "/home/hacui/repos/andes/examples"
Loaded config from file "/home/hacui/.andes/andes.rc"

                a=(0, 2, 3, 4),
                ytimes=60,
                )
```

```
(<Figure size 600x400 with 1 Axes>, <AxesSubplot:xlabel='Time [s]')>)
```

## 2.9.2 Adjusting Load to Compensate for the Generation Loss

Check the power of the lost generator by inspecting the power flow inputs:

```
ss.PV.as_df()
```

	idx	u	name	Sn	Vn	bus	busr	p0	q0	pmax	pmin	qmax	\
uid													
0	2	0.0	2	100.0	69.0	2	None	0.40	0.15	0.5	0.1	0.15	
1	3	0.0	3	100.0	69.0	3	None	0.40	0.15	0.5	0.1	0.15	
2	4	0.0	4	100.0	138.0	6	None	0.30	0.10	0.5	0.1	0.10	
3	5	0.0	5	100.0	69.0	8	None	0.35	0.10	0.5	0.1	0.10	

	qmin	v0	vmax	vmin	ra	xs
uid						
0	-0.40	1.03	1.4	0.6	0.0	0.13
1	-0.10	1.01	1.4	0.6	0.0	0.13
2	-0.06	1.03	1.4	0.6	0.0	0.12
3	-0.06	1.03	1.4	0.6	0.0	0.12

The tripped GENROU\_2 correspond to the first PV (GENROU\_1 corresponds to Slack). Thus, the lost active power is 0.40 pu.

Let's compensate for that by shedding 0.4 pu of active power load at t=2.0 s.

By checking the equation documentation of PQ (using `print(ss.PQ.doc())`), we can tell that the imposed active power for time-domain simulation is from `Ppf`, because we used the constant power model with `p2p = 1`.

### Algebraic Equations

Name	Type	RHS of Equation " $0 = g(x, y)$ "
a	ExtAlgeb	$u * (dae\_t \leq 0) * (p0 * vcmp\_zi + Rlb * vcmp\_zl * v^{**2} + Rub * vcmp\_zu * v^{**2}) + u * (dae\_t > 0) * (p2p * Ppf + p2i * Ipeq * v + p2z * Req * v^{**2})$
v	ExtAlgeb	$u * (dae\_t \leq 0) * (q0 * vcmp\_zi + Xlb * vcmp\_zl * v^{**2} + Xub * vcmp\_zu * v^{**2}) + u * (dae\_t > 0) * (q2q * Qpf + q2i * Ipeq * v + q2z * Xeq * v^{**2})$

`Ppf` may be different from `p0` specified in the data file.

```
# active power from power flow solution - make a copy
```

```
Ppf = np.array(ss.PQ.Ppf.v)
```

```
Ppf
```

```
array([0.217, 0.5 , 0.478, 0.076, 0.15 , 0.295, 0.09 , 0.035, 0.061,
       0.135, 0.2  ])
```

Reload the system and add the generator trip.

```
ss = andes.load(ieee14_raw, addfile=ieee14_dyr, setup=False)

ss.add("Toggler", dict(model='SynGen', dev="GENROU_2", t=1.0))
ss.setup()
ss.Toggler.u.v[[0, 1]] = 0

ss.PQ.config.p2p = 1
ss.PQ.config.q2q = 1
ss.PQ.config.p2z = 0
ss.PQ.config.q2z = 0
ss.PQ.pq2z = 0

ss.PFlow.run()
```

```

"/home/hacui/repos/andes/examples/ieee14\_out.txt" removed.

"/home/hacui/repos/andes/examples/ieee14\_out.lst" removed.

"/home/hacui/repos/andes/examples/ieee14\_out.npz" removed.

The result shows the generator speed (frequency) returns to 60 Hz after load shedding.

## 2.10 Profile in Notebook

### 2.10.1 Profiling with Python CProfiler

Before getting started, this example requires the config flag `PFlow.init_tds` to be `0`, which is the default value.

```
import andes
from andes.utils.paths import get_case

case_path = get_case('kundur/kundur_full.xlsx')
```

Passing `profile=True`, `no_output = True` to run will enable the profiler and have the results printed.

```
ss = andes.run(case_path, profile=True, routine='tds', no_output=True)
```

```
Working directory: "/home/hacui/repos/andes/examples"
Loaded config from file "/home/hacui/.andes/andes.rc"
Loaded generated Python code in "/home/hacui/.andes/pycode".
Parsing input file "/home/hacui/repos/andes/andes/cases/kundur/kundur_full.xlsx".
→...
Input file parsed in 0.2928 seconds.
System internal structure set up in 0.0339 seconds.
-> System connectivity check results:
    No islanded bus detected.
    A total of 1 island(s) detected.
    Each island has a slack bus correctly defined and enabled.

-> Power flow calculation
    Sparse solver: KLU
    Solution method: NR method
Numba compilation initiated with caching.
Power flow initialized in 0.2752 seconds.
0: |F(x)| = 14.9282832
1: |F(x)| = 3.608627841
2: |F(x)| = 3.371691245
3: |F(x)| = 3.38335788
4: |F(x)| = 1.643469337
5: |F(x)| = 0.2341714002
6: |F(x)| = 0.03397375079

## 2.10.2 Profiling with line\_profiler.

line\_profiler provides line-based profiling results for functions.

Install with `pip install line_profiler` and restart the notebook.

```

import andes
from andes.utils.paths import get_case

case_path = get_case('kundur/kundur_full.xlsx')

```

### Profile power flow

Pass the function name to profile to the magic `%lprun`, followed by a call to the function itself or an upper-level function.

Results will be shown in a popup window.

```

%load_ext line_profiler

%lprun -f andes.routines.pflow.PFlow.run andes.run(case_path, no_output=True,
↳default_config=True)

```

```

Working directory: "/home/hacui/repos/andes/examples"
Reloaded generated Python code of module "pycode".
Parsing input file "/home/hacui/repos/andes/andes/cases/kundur/kundur_full.xlsx".
↪...
Input file parsed in 0.0882 seconds.
System internal structure set up in 0.0450 seconds.
-> System connectivity check results:
    No islanded bus detected.
    A total of 1 island(s) detected.
    Each island has a slack bus correctly defined and enabled.

-> Power flow calculation
    Sparse solver: KLU
    Solution method: NR method
Power flow initialized in 0.0064 seconds.
0: |F(x)| = 14.9282832
1: |F(x)| = 3.608627841
2: |F(x)| = 0.1701107882
3: |F(x)| = 0.002038626956
4: |F(x)| = 3.745103977e-07
Converged in 5 iterations in 0.0050 seconds.

```

```

-> Single process finished in 0.3018 seconds.

```

Alternatively, do

```

ss = andes.run(case_path, no_output=True, default_config=True)

```

```

## 3.1 ACLine

Common Parameters: u, name, bus1, bus2, r, x

Common Variables: v1, v2, a1, a2

Available models: *Line*

### 3.1.1 Line

Group *ACLine*

AC transmission line model.

To reduce the number of variables, line injections are summed at bus equations and are not stored. Current injections are not computed.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus1		idx of from bus			
bus2		idx of to bus			
Sn	$S_n$	Power rating	100	<i>MW</i>	non_zero
fn	$f$	rated frequency	60	<i>Hz</i>	
Vn1	$V_{n1}$	AC voltage rating	110	<i>kV</i>	non_zero
Vn2	$V_{n2}$	rated voltage of bus2	110	<i>kV</i>	non_zero
r	$r$	line resistance	0.000	<i>p.u.</i>	z
x	$x$	line reactance	0.000	<i>p.u.</i>	z
b		shared shunt susceptance	0	<i>p.u.</i>	y
g		shared shunt conductance	0	<i>p.u.</i>	y
b1	$b_1$	from-side susceptance	0	<i>p.u.</i>	y
g1	$g_1$	from-side conductance	0	<i>p.u.</i>	y
b2	$b_2$	to-side susceptance	0	<i>p.u.</i>	y
g2	$g_2$	to-side conductance	0	<i>p.u.</i>	y
trans		transformer branch flag	0	<i>bool</i>	
tap	$t_{ap}$	transformer branch tap ratio	1	<i>float</i>	non_negative
phi	$\phi$	transformer branch phase shift in rad	0	<i>radian</i>	
owner		owner code			
xcoord		x coordinates			
ycoord		y coordinates			

## Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
a1	$a_1$	ExtAlgeb	phase angle of the from bus		
a2	$a_2$	ExtAlgeb	phase angle of the to bus		
v1	$v_1$	ExtAlgeb	voltage magnitude of the from bus		
v2	$v_2$	ExtAlgeb	voltage magnitude of the to bus		

## Variable Initialization Equations

Name	Symbol	Type	Initial Value
a1	$a_1$	ExtAlgeb	
a2	$a_2$	ExtAlgeb	
v1	$v_1$	ExtAlgeb	
v2	$v_2$	ExtAlgeb	

## Algebraic Equations

Name	Sym- bol	Type	RHS of Equation "0 = g(x, y)"
a1	$a_1$	ExtAl- geb	$u \left( -1/t_{ap} v_1 v_2 \left( -b_{hk} \sin(\phi - a_1 + a_2) + g_{hk} \cos(\phi - a_1 + a_2) \right) + 1/t_{ap}^2 v_1^2 (g_h + g_{hk}) \right)$
a2	$a_2$	ExtAl- geb	$u \left( -1/t_{ap} v_1 v_2 \left( b_{hk} \sin(\phi - a_1 + a_2) + g_{hk} \cos(\phi - a_1 + a_2) \right) + v_2^2 (g_h + g_{hk}) \right)$
v1	$v_1$	ExtAl- geb	$u \left( -1/t_{ap} v_1 v_2 \left( -b_{hk} \cos(\phi - a_1 + a_2) - g_{hk} \sin(\phi - a_1 + a_2) \right) - 1/t_{ap}^2 v_1^2 (b_h + b_{hk}) \right)$
v2	$v_2$	ExtAl- geb	$u \left( 1/t_{ap} v_1 v_2 \left( b_{hk} \cos(\phi - a_1 + a_2) - g_{hk} \sin(\phi - a_1 + a_2) \right) - v_2^2 (b_h + b_{hk}) \right)$

### Services

Name	Symbol	Equation	Type
gh	$g_h$	$0.5g + g_1$	ConstService
bh	$b_h$	$0.5b + b_1$	ConstService
gk	$g_k$	$0.5g + g_2$	ConstService
bk	$b_k$	$0.5b + b_2$	ConstService
yh	$y_h$	$u (ib_h + g_h)$	ConstService
yk	$y_k$	$u (ib_k + g_k)$	ConstService
yhk	$y_{hk}$	$\frac{u}{r+i(x+1.0 \cdot 10^{-8})+1.0 \cdot 10^{-8}}$	ConstService
ghk	$g_{hk}$	$\text{re}(y_{hk})$	ConstService
bhk	$b_{hk}$	$\text{im}(y_{hk})$	ConstService
itap	$1/t_{ap}$	$\frac{1}{t_{ap}}$	ConstService
itap2	$1/t_{ap}^2$	$\frac{1}{t_{ap}^2}$	ConstService

### Config Fields in [Line]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.2 ACShort

Common Parameters: u, name, bus1, bus2

Common Variables: v1, v2, a1, a2

Available models: *Jumper*

### 3.2.1 Jumper

Group *ACShort*

Jumper is a device to short two buses (merging two buses into one).

Jumper can connect two buses satisfying one of the following conditions:

- neither bus is voltage-controlled
- either bus is voltage-controlled
- both buses are voltage-controlled, and the voltages are the same.

If the buses are controlled in different voltages, power flow will not solve (as the power flow through the jumper will be infinite).

In the solutions, the  $p$  and  $q$  are flowing out of bus1 and flowing into bus2.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus1		idx of from bus			
bus2		idx of to bus			

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
$p$	$P$	Algeb	active power (1 to 2)		
$q$	$Q$	Algeb	active power (1 to 2)		
$a1$	$a_1$	ExtAlgeb	phase angle of the from bus		
$a2$	$a_2$	ExtAlgeb	phase angle of the to bus		
$v1$	$v_1$	ExtAlgeb	voltage magnitude of the from bus		
$v2$	$v_2$	ExtAlgeb	voltage magnitude of the to bus		

Variable Initialization Equations

Name	Symbol	Type	Initial Value
$p$	$P$	Algeb	
$q$	$Q$	Algeb	
$a1$	$a_1$	ExtAlgeb	
$a2$	$a_2$	ExtAlgeb	
$v1$	$v_1$	ExtAlgeb	
$v2$	$v_2$	ExtAlgeb	

Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
p	$P$	Algeb	$u(a_1 - a_2)$
q	$Q$	Algeb	$u(v_1 - v_2)$
a1	$a_1$	ExtAlgeb	$P$
a2	$a_2$	ExtAlgeb	$-P$
v1	$v_1$	ExtAlgeb	$Q$
v2	$v_2$	ExtAlgeb	$-Q$

Config Fields in [Jumper]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.3 ACTopology

Common Parameters: u, name

Common Variables: a, v

Available models: *Bus*

### 3.3.1 Bus

Group *ACTopology*

AC Bus model.

Power balance equation have the form of `load - injection = 0`. Namely, load is positively summed, while injections are negative.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
Vn	$V_n$	AC voltage rating	110	<i>kV</i>	non_zero
vmax	$V_{max}$	Voltage upper limit	1.100	<i>p.u.</i>	
vmin	$V_{min}$	Voltage lower limit	0.900	<i>p.u.</i>	
v0	$V_0$	initial voltage magnitude	1	<i>p.u.</i>	non_zero
a0	$\theta_0$	initial voltage phase angle	0	<i>rad</i>	
xcoord		x coordinate (longitude)	0		
ycoord		y coordinate (latitude)	0		
area		Area code			
zone		Zone code			
owner		Owner code			

## Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
a	$\theta$	Algeb	voltage angle	<i>rad</i>	v_str
v	$V$	Algeb	voltage magnitude	<i>p.u.</i>	v_str

## Variable Initialization Equations

Name	Symbol	Type	Initial Value
a	$\theta$	Algeb	$\theta_0 \cdot (1 - z_{flat}) + 1.0 \cdot 10^{-8} z_{flat}$
v	$V$	Algeb	$V_0 \cdot (1 - z_{flat}) + z_{flat}$

## Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
a	$\theta$	Algeb	0
v	$V$	Algeb	0

## Config Fields in [Bus]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)
flat_start	$z_{flat}$	0	flat start for voltages	(0, 1)

## 3.4 Calculation

Group of classes that calculates based on other models.

Common Parameters: `u`, `name`

Available models: *ACE*, *ACEc*, *COI*

### 3.4.1 ACE

Group *Calculation*

Area Control Error model.

Discrete frequency sampling. System base frequency from `system.config.freq` is used.

Frequency sampling period (in seconds) can be specified in `ACE.config.interval`. The sampling start time (in seconds) can be specified in `ACE.config.offset`.

Note: area idx is automatically retrieved from *bus*.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	<i>u</i>	connection status	1	<i>bool</i>	
name		device name			
bus		bus idx for freq. measurement			mandatory
bias	$\beta$	bias parameter	1	<i>MW/0.1Hz</i>	power
busf		Optional BusFreq device idx			
area			0		

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
ace	<i>ace</i>	Algeb	area control error	<i>p.u. (MW)</i>	
f	<i>f</i>	ExtAlgeb	Bus frequency	<i>p.u. (Hz)</i>	

Variable Initialization Equations

Name	Symbol	Type	Initial Value
ace	<i>ace</i>	Algeb	
f	<i>f</i>	ExtAlgeb	

Algebraic Equations

Name	Symbol	Type	RHS of Equation " $0 = g(x, y)$ "
ace	<i>ace</i>	Algeb	$10 \cdot 1 / S_{b,sys} \beta f_{sys} (v_s^f - 1) - ace$
f	<i>f</i>	ExtAlgeb	0

## Services

Name	Symbol	Equation	Type
imva	$1/S_{b,sys}$	$\frac{1}{S_{b,sys}}$	ConstService

## Discrete

Name	Symbol	Type	Info
fs	$f_s$	Sampling	Sampled freq.

## Config Fields in [ACE]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)
freq_model		BusFreq	default freq. measurement model	('BusFreq',)
interval		4	sampling time interval	
offset		0	sampling time offset	

## 3.4.2 ACEc

Group *Calculation*

Area Control Error model.

Continuous frequency sampling. System base frequency from `system.config.freq` is used.

Note: area idx is automatically retrieved from *bus*.

## Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		bus idx for freq. measurement			mandatory
bias	$\beta$	bias parameter	1	<i>MW/0.1Hz</i>	power
busf		Optional BusFreq device idx			
area			0		

## Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
ace	$ace$	Algeb	area control error	<i>p.u. (MW)</i>	
f	$f$	ExtAlgeb	Bus frequency	<i>p.u. (Hz)</i>	

## Variable Initialization Equations

Name	Symbol	Type	Initial Value
ace	$ace$	Algeb	
f	$f$	ExtAlgeb	

## Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
ace	$ace$	Algeb	$10 \cdot 1/S_{b,sys} \beta f_{sys} (f - 1) - ace$
f	$f$	ExtAlgeb	0

## Services

Name	Symbol	Equation	Type
imva	$1/S_{b,sys}$	$\frac{1}{S_{b,sys}}$	ConstService

## Config Fields in [ACEc]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)
freq_model		BusFreq	default freq. measurement model	('BusFreq',)

### 3.4.3 COI

Group *Calculation*

Center of inertia calculation class.

## Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
M		Linearly stored SynGen.M	0		

## Variables (States + Algebraics)

Name	Sym- bol	Type	Description	Unit	Properties
wgen	$\omega_{gen}$	ExtState	Linearly stored SynGen.omega		
agen	$\delta_{gen}$	ExtState	Linearly stored SynGen.delta		
omega	$\omega_{coi}$	Algeb	COI speed		v_str,v_setter
delta	$\delta_{coi}$	Algeb	COI rotor angle		v_str,v_setter
omega_sub	$\omega_{sub}$	ExtAl- geb	COI frequency contribution of each genera- tor		
delta_sub	$\delta_{sub}$	ExtAl- geb	COI angle contribution of each generator		

### Variable Initialization Equations

Name	Symbol	Type	Initial Value
wgen	$\omega_{gen}$	ExtState	
agen	$\delta_{gen}$	ExtState	
omega	$\omega_{coi}$	Algeb	$\omega_{gen,0,avg}$
delta	$\delta_{coi}$	Algeb	$\delta_{gen,0,avg}$
omega_sub	$\omega_{sub}$	ExtAlgeb	
delta_sub	$\delta_{sub}$	ExtAlgeb	

### Differential Equations

Name	Symbol	Type	RHS of Equation "T x' = f(x, y)"	T (LHS)
wgen	$\omega_{gen}$	ExtState	0	
agen	$\delta_{gen}$	ExtState	0	

### Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
omega	$\omega_{coi}$	Algeb	$-\omega_{coi}$
delta	$\delta_{coi}$	Algeb	$-\delta_{coi}$
omega_sub	$\omega_{sub}$	ExtAlgeb	$M_w \omega_{gen}$
delta_sub	$\delta_{sub}$	ExtAlgeb	$M_w \delta_{gen}$

### Services

Name	Symbol	Equation	Type
Mw	$M_w$	$\frac{M}{M_{tr}}$	ConstService
d0w	$\delta_{gen,0,w}$	$M_w \delta_{gen,0}$	ConstService
a0w	$\omega_{gen,0,w}$	$M_w \omega_{gen,0}$	ConstService

### Config Fields in [COI]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.5 Collection

Collection of topology models

Common Parameters: u, name

Available models: *Area*

### 3.5.1 Area

Group *Collection*

Area model.

Area collects back references from the Bus model and the ACTopology group.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	<i>u</i>	connection status	1	<i>bool</i>	
name		device name			

Config Fields in [Area]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.6 DCLink

Basic DC links

Common Parameters: u, name

Available models: *Ground, R, L, C, RCp, RCs, RLs, RLCs, RLCp*

### 3.6.1 Ground

Group *DCLink*

Ground model that sets the voltage of the connected DC node.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
node		Node index			mandatory
voltage	$V_0$	Ground voltage (typically 0)	0	<i>p.u.</i>	

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
Idc	$I_{dc}$	Algeb	Fictitious current injection from ground		v_str
v	$v$	ExtAlgeb			

Variable Initialization Equations

Name	Symbol	Type	Initial Value
Idc	$I_{dc}$	Algeb	0
v	$v$	ExtAlgeb	

Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
Idc	$I_{dc}$	Algeb	$u(-V_0 + v)$
v	$v$	ExtAlgeb	$-I_{dc}$

Config Fields in [Ground]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

### 3.6.2 R

Group *DCLink*

Resistive dc line

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
node1		Node 1 index			mandatory
node2		Node 2 index			mandatory
Vdcn1	$V_{dcn1}$	DC voltage rating on node 1	100	<i>kV</i>	non_zero
Vdcn2	$V_{dcn2}$	DC voltage rating on node 2	100	<i>kV</i>	non_zero
Idcn	$I_{dcn}$	DC current rating	1	<i>kA</i>	non_zero
R		DC line resistance	0.010	<i>p.u.</i>	non_zero,r

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
Idc	$I_{dc}$	Algeb	Current from node 2 to 1	<i>p.u.</i>	v_str
v1	$v_1$	ExtAlgeb	DC voltage on node 1		
v2	$v_2$	ExtAlgeb	DC voltage on node 2		

Variable Initialization Equations

Name	Symbol	Type	Initial Value
Idc	$I_{dc}$	Algeb	$\frac{u(-v_1+v_2)}{R}$
v1	$v_1$	ExtAlgeb	
v2	$v_2$	ExtAlgeb	

Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
Idc	$I_{dc}$	Algeb	$-I_{dc} + \frac{u(-v_1+v_2)}{R}$
v1	$v_1$	ExtAlgeb	$-I_{dc}$
v2	$v_2$	ExtAlgeb	$I_{dc}$

Config Fields in [R]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

### 3.6.3 L

Group *DCLink*

Inductive dc line

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
node1		Node 1 index			mandatory
node2		Node 2 index			mandatory
Vdcn1	$V_{dcn1}$	DC voltage rating on node 1	100	<i>kV</i>	non_zero
Vdcn2	$V_{dcn2}$	DC voltage rating on node 2	100	<i>kV</i>	non_zero
Idcn	$I_{dcn}$	DC current rating	1	<i>kA</i>	non_zero
L		DC line inductance	0.001	<i>p.u.</i>	non_zero,r

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
IL	$I_L$	State	Inductance current	<i>p.u.</i>	v_str
v1	$v_1$	ExtAlgeb	DC voltage on node 1		
v2	$v_2$	ExtAlgeb	DC voltage on node 2		

Variable Initialization Equations

Name	Symbol	Type	Initial Value
IL	$I_L$	State	0
v1	$v_1$	ExtAlgeb	
v2	$v_2$	ExtAlgeb	

Differential Equations

Name	Symbol	Type	RHS of Equation "T x' = f(x, y)"	T (LHS)
IL	$I_L$	State	$-u(v_1 - v_2)$	

Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
v1	$v_1$	ExtAlgeb	$-I_L$
v2	$v_2$	ExtAlgeb	$I_L$

Config Fields in [L]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

### 3.6.4 C

Group *DCLink*

Capacitive dc branch

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
node1		Node 1 index			mandatory
node2		Node 2 index			mandatory
Vdcn1	$V_{dcn1}$	DC voltage rating on node 1	100	<i>kV</i>	non_zero
Vdcn2	$V_{dcn2}$	DC voltage rating on node 2	100	<i>kV</i>	non_zero
Idcn	$I_{dcn}$	DC current rating	1	<i>kA</i>	non_zero
C		DC capacitance	0.001	<i>p.u.</i>	non_zero,g

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
vC	$v_C$	State	Capacitor current	<i>p.u.</i>	v_str
Idc	$I_{dc}$	Algeb	Current from node 2 to 1	<i>p.u.</i>	v_str
v1	$v_1$	ExtAlgeb	DC voltage on node 1		
v2	$v_2$	ExtAlgeb	DC voltage on node 2		

Variable Initialization Equations

Name	Symbol	Type	Initial Value
vC	$v_C$	State	0
Idc	$I_{dc}$	Algeb	0
v1	$v_1$	ExtAlgeb	
v2	$v_2$	ExtAlgeb	

Differential Equations

Name	Symbol	Type	RHS of Equation "T x' = f(x, y)"	T (LHS)
vC	$v_C$	State	$-I_{dc}u$	

## Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
Idc	$I_{dc}$	Algeb	$I_{dc}(1 - u) + u(-v_1 + v_2 + v_C)$
v1	$v_1$	ExtAlgeb	$-I_{dc}$
v2	$v_2$	ExtAlgeb	$I_{dc}$

## Config Fields in [C]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.6.5 RCp

Group *DCLink*

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
node1		Node 1 index			mandatory
node2		Node 2 index			mandatory
Vdcn1	$V_{dcn1}$	DC voltage rating on node 1	100	<i>kV</i>	non_zero
Vdcn2	$V_{dcn2}$	DC voltage rating on node 2	100	<i>kV</i>	non_zero
Idcn	$I_{dcn}$	DC current rating	1	<i>kA</i>	non_zero
R	$R$	DC line resistance	0.010	<i>p.u.</i>	non_zero,r
C	$C$	DC capacitance	0.001	<i>p.u.</i>	non_zero,g

## Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
vC	$v_C$	State	Capacitor current	<i>p.u.</i>	v_str
Idc	$I_{dc}$	Algeb	Current from node 2 to 1	<i>p.u.</i>	v_str
v1	$v_1$	ExtAlgeb	DC voltage on node 1		
v2	$v_2$	ExtAlgeb	DC voltage on node 2		

## Variable Initialization Equations

Name	Symbol	Type	Initial Value
vC	$v_C$	State	$v_1 - v_2$
Idc	$I_{dc}$	Algeb	$\frac{-v_1 + v_2}{R}$
v1	$v_1$	ExtAlgeb	
v2	$v_2$	ExtAlgeb	

## Differential Equations

Name	Symbol	Type	RHS of Equation "T x' = f(x, y)"	T (LHS)
vC	$v_C$	State	$-u \left( I_{dc} - \frac{v_C}{R} \right)$	$C$

## Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
Idc	$I_{dc}$	Algeb	$I_{dc} (1 - u) + u (-v_1 + v_2 + v_C)$
v1	$v_1$	ExtAlgeb	$-I_{dc}$
v2	$v_2$	ExtAlgeb	$I_{dc}$

## Config Fields in [RCp]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.6.6 RCs

Group *DCLink*

## Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
node1		Node 1 index			mandatory
node2		Node 2 index			mandatory
Vdcn1	$V_{dcn1}$	DC voltage rating on node 1	100	<i>kV</i>	non_zero
Vdcn2	$V_{dcn2}$	DC voltage rating on node 2	100	<i>kV</i>	non_zero
Idcn	$I_{dcn}$	DC current rating	1	<i>kA</i>	non_zero
R	$R$	DC line resistance	0.010	<i>p.u.</i>	non_zero,r
C	$C$	DC capacitance	0.001	<i>p.u.</i>	non_zero,g

## Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
vC	$v_C$	State	Capacitor current	$p.u.$	v_str
Idc	$I_{dc}$	Algeb	Current from node 2 to 1	$p.u.$	v_str
v1	$v_1$	ExtAlgeb	DC voltage on node 1		
v2	$v_2$	ExtAlgeb	DC voltage on node 2		

### Variable Initialization Equations

Name	Symbol	Type	Initial Value
vC	$v_C$	State	$v_1 - v_2$
Idc	$I_{dc}$	Algeb	$\frac{-v_1 + v_2}{R}$
v1	$v_1$	ExtAlgeb	
v2	$v_2$	ExtAlgeb	

### Differential Equations

Name	Symbol	Type	RHS of Equation "T x' = f(x, y)"	T (LHS)
vC	$v_C$	State	$-I_{dc}u$	$C$

### Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
Idc	$I_{dc}$	Algeb	$I_{dc}(1 - u) + u(-I_{dc}R - v_1 + v_2 + v_C)$
v1	$v_1$	ExtAlgeb	$-I_{dc}$
v2	$v_2$	ExtAlgeb	$I_{dc}$

### Config Fields in [RCs]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.6.7 RLs

Group *DCLink*

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
node1		Node 1 index			mandatory
node2		Node 2 index			mandatory
Vdcn1	$V_{dcn1}$	DC voltage rating on node 1	100	<i>kV</i>	non_zero
Vdcn2	$V_{dcn2}$	DC voltage rating on node 2	100	<i>kV</i>	non_zero
Idcn	$I_{dcn}$	DC current rating	1	<i>kA</i>	non_zero
R	$R$	DC line resistance	0.010	<i>p.u.</i>	non_zero,r
L	$L$	DC line inductance	0.001	<i>p.u.</i>	non_zero,r

## Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
IL	$I_L$	State	Inductance current	<i>p.u.</i>	v_str
Idc	$I_{dc}$	Algeb	Current from node 2 to 1	<i>p.u.</i>	v_str
v1	$v_1$	ExtAlgeb	DC voltage on node 1		
v2	$v_2$	ExtAlgeb	DC voltage on node 2		

## Variable Initialization Equations

Name	Symbol	Type	Initial Value
IL	$I_L$	State	$\frac{v_1 - v_2}{R}$
Idc	$I_{dc}$	Algeb	$-\frac{u(v_1 - v_2)}{R}$
v1	$v_1$	ExtAlgeb	
v2	$v_2$	ExtAlgeb	

## Differential Equations

Name	Symbol	Type	RHS of Equation "T x' = f(x, y)"	T (LHS)
IL	$I_L$	State	$u(-I_L R + v_1 - v_2)$	$L$

## Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
Idc	$I_{dc}$	Algeb	$-I_L u - I_{dc}$
v1	$v_1$	ExtAlgeb	$-I_{dc}$
v2	$v_2$	ExtAlgeb	$I_{dc}$

## Config Fields in [RLs]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

### 3.6.8 RLCs

Group *DCLink*

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
node1		Node 1 index			mandatory
node2		Node 2 index			mandatory
Vdcn1	$V_{dcn1}$	DC voltage rating on node 1	100	<i>kV</i>	non_zero
Vdcn2	$V_{dcn2}$	DC voltage rating on node 2	100	<i>kV</i>	non_zero
Idcn	$I_{dcn}$	DC current rating	1	<i>kA</i>	non_zero
R	$R$	DC line resistance	0.010	<i>p.u.</i>	non_zero,r
L	$L$	DC line inductance	0.001	<i>p.u.</i>	non_zero,r
C	$C$	DC capacitance	0.001	<i>p.u.</i>	non_zero,g

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
IL	$I_L$	State	Inductance current	<i>p.u.</i>	v_str
vC	$v_C$	State	Capacitor current	<i>p.u.</i>	v_str
Idc	$I_{dc}$	Algeb	Current from node 2 to 1	<i>p.u.</i>	v_str
v1	$v_1$	ExtAlgeb	DC voltage on node 1		
v2	$v_2$	ExtAlgeb	DC voltage on node 2		

Variable Initialization Equations

Name	Symbol	Type	Initial Value
IL	$I_L$	State	0
vC	$v_C$	State	$v_1 - v_2$
Idc	$I_{dc}$	Algeb	0
v1	$v_1$	ExtAlgeb	
v2	$v_2$	ExtAlgeb	

Differential Equations

Name	Symbol	Type	RHS of Equation "T x' = f(x, y)"	T (LHS)
IL	$I_L$	State	$u(-I_L R + v_1 - v_2 - v_C)$	$L$
vC	$v_C$	State	$I_L u$	$C$

## Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
Idc	$I_{dc}$	Algeb	$-I_L - I_{dc}$
v1	$v_1$	ExtAlgeb	$-I_{dc}$
v2	$v_2$	ExtAlgeb	$I_{dc}$

## Config Fields in [RLCs]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.6.9 RLCp

Group *DCLink*

## Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
node1		Node 1 index			mandatory
node2		Node 2 index			mandatory
Vdcn1	$V_{dcn1}$	DC voltage rating on node 1	100	<i>kV</i>	non_zero
Vdcn2	$V_{dcn2}$	DC voltage rating on node 2	100	<i>kV</i>	non_zero
Idcn	$I_{dcn}$	DC current rating	1	<i>kA</i>	non_zero
R	$R$	DC line resistance	0.010	<i>p.u.</i>	non_zero,r
L	$L$	DC line inductance	0.001	<i>p.u.</i>	non_zero,r
C	$C$	DC capacitance	0.001	<i>p.u.</i>	non_zero,g

## Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
IL	$I_L$	State	Inductance current	<i>p.u.</i>	v_str
vC	$v_C$	State	Capacitor current	<i>p.u.</i>	v_str
Idc	$I_{dc}$	Algeb	Current from node 2 to 1	<i>p.u.</i>	v_str
v1	$v_1$	ExtAlgeb	DC voltage on node 1		
v2	$v_2$	ExtAlgeb	DC voltage on node 2		

## Variable Initialization Equations

Name	Symbol	Type	Initial Value
IL	$I_L$	State	0
vC	$v_C$	State	$v_1 - v_2$
Idc	$I_{dc}$	Algeb	$\frac{-v_1 + v_2}{R}$
v1	$v_1$	ExtAlgeb	
v2	$v_2$	ExtAlgeb	

## Differential Equations

Name	Symbol	Type	RHS of Equation "T x' = f(x, y)"	T (LHS)
IL	$I_L$	State	$uv_C$	$L$
vC	$v_C$	State	$-u \left( -I_L + I_{dc} - \frac{v_C}{R} \right)$	$C$

## Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
Idc	$I_{dc}$	Algeb	$I_{dc} (1 - u) + u (-v_1 + v_2 + v_C)$
v1	$v_1$	ExtAlgeb	$-I_{dc}$

## Config Fields in [RLCp]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.7 DCTopology

Common Parameters: u, name

Common Variables: v

Available models: *Node*

### 3.7.1 Node

Group *DCTopology*

DC Node model.

A DC Node is like an AC Bus. DC devices need to be connected to Nodes to inject power flow.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
Vdcn	$V_{dcn}$	DC voltage rating	100	<i>kV</i>	non_zero
Idcn	$I_{dcn}$	DC current rating	1	<i>kA</i>	non_zero
v0	$V_{dc0}$	initial voltage magnitude	1	<i>p.u.</i>	
xcoord		x coordinate (longitude)	0		
ycoord		y coordinate (latitude)	0		
area		Area code			
zone		Zone code			
owner		Owner code			

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
v	$V_{dc}$	Algeb	voltage magnitude	<i>p.u.</i>	v_str

Variable Initialization Equations

Name	Symbol	Type	Initial Value
v	$V_{dc}$	Algeb	$V_{dc0} \cdot (1 - z_{flat}) + z_{flat}$

Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
v	$V_{dc}$	Algeb	0

Config Fields in [Node]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)
flat_start	$z_{flat}$	0	flat start for voltages	(0, 1)

## 3.8 DG

Distributed generation (small-scale).

Common Parameters: *u*, *name*, *bus*, *fn*

Available models: *PVD1*, *ESD1*, *EVI*, *EV2*

### 3.8.1 PVD1

Group *DG*

WECC Distributed PV model.

Device power rating is specified in  $S_n$ . Output currents are named  $I_{pout\_y}$  and  $I_{qout\_y}$ . Output power can be computed as  $P_e = I_{pout\_y} * v$  and  $Q_e = I_{qout\_y} * v$ .

Frequency tripping response points  $ft0$ ,  $ft1$ ,  $ft2$ , and  $ft3$  must be monotonically increasing. Same rule applies to the voltage tripping response points  $vt0$ ,  $vt1$ ,  $vt2$ , and  $vt3$ . The program does not check these values, and the user is responsible for the parameter validity.

Frequency and voltage recovery latching is yet to be implemented.

Modifications to the active and reactive power references, typically by an external scheduling program, should write to  $pref0.v$  and  $qref0.v$  in place. AGC signals should write to  $pext0.v$  in place.

Maximum power limit  $pmx$  can be enabled by editing the configuration file by setting  $plim=1$ . It cannot be modified in runtime.

Reference: [1] ESIG, WECC Distributed and Small PV Plants Generic Model (PVD1), [Online], Available:

<https://www.esig.energy/wiki-main-page/wecc-distributed-and-small-pv-plants-generic-model-pvd1/>

Parameters

Name	Symbol	Description	Default	Unit	Properties
<i>idx</i>		unique device idx			
<i>u</i>	$u$	connection status	1	<i>bool</i>	
<i>name</i>		device name			
<i>bus</i>		interface bus id			mandatory
<i>gen</i>		static generator index			mandatory
$S_n$	$S_n$	device MVA rating	100	<i>MVA</i>	
<i>fn</i>	$f_n$	nominal frequency	60	<i>Hz</i>	
<i>busf</i>		Optional BusFreq measurement device idx			
<i>xc</i>	$x_c$	coupling reactance	0	<i>p.u.</i>	<i>z</i>
<i>pqflag</i>		P/Q priority for I limit; 0-Q priority, 1-P priority		<i>bool</i>	mandatory
<i>igreg</i>		Remote bus idx for droop response, None for local			
<i>qmx</i>	$q_{mx}$	Max. reactive power command	0.330	<i>pu</i>	power

continues

Table 2 – continued from previous page

Name	Symbol	Description	Default	Unit	Properties
qmn	$q_{mn}$	Min. reactive power command	-0.330	$pu$	power
pmx	$p_{mx}$	maximum power limit	999	$pu$	power
v0	$v_0$	Lower limit of deadband for Vdroop response	0.800	$pu$	non_zero
v1	$v_1$	Upper limit of deadband for Vdroop response	1.100	$pu$	non_zero
dqdv	$dq/dv$	Q-V droop characteristics (negative)	-1		non_zero,power
fdbd	$f_{dbd}$	frequency deviation deadband	-0.017	$Hz$	non_positive
ddn	$D_{dn}$	Gain after f deadband	0	$pu (MW)/Hz$	non_negative,po
ialim	$I_{alim}$	Apparent power limit	1.300		non_zero,non_n
vt0	$V_{t0}$	Voltage tripping response curve point 0	0.880	$p.u.$	non_zero,non_n
vt1	$V_{t1}$	Voltage tripping response curve point 1	0.900	$p.u.$	non_zero,non_n
vt2	$V_{t2}$	Voltage tripping response curve point 2	1.100	$p.u.$	non_zero,non_n
vt3	$V_{t3}$	Voltage tripping response curve point 3	1.200	$p.u.$	non_zero,non_n
vrflag	$z_{VR}$	V-trip is latching (0) or self-resetting (0-1)	0		
ft0	$f_{t0}$	Frequency tripping response curve point 0	59.500	$Hz$	non_zero,non_n
ft1	$f_{t1}$	Frequency tripping response curve point 1	59.700	$Hz$	non_zero,non_n
ft2	$f_{t2}$	Frequency tripping response curve point 2	60.300	$Hz$	non_zero,non_n
ft3	$f_{t3}$	Frequency tripping response curve point 3	60.500	$Hz$	non_zero,non_n
frflag	$z_{FR}$	f-trip is latching (0) or self-resetting (0-1)	0		
tip	$T_{ip}$	Inverter active current lag time constant	0.020	$s$	non_negative
tiq	$T_{iq}$	Inverter reactive current lag time constant	0.020	$s$	non_negative
gammap	$\gamma_p$	Ratio of PVD1.pref0 w.r.t to that of static PV	1		
gammaq	$\gamma_q$	Ratio of PVD1.qref0 w.r.t to that of static PV	1		
recflag	$z_{rec}$	Enable flag for voltage and frequency recovery limiters	1

## 3.8.2 ESD1

### Group *DG*

Distributed energy storage model.

A state-of-charge limit is added to the PVD1 model. This limit is applied to Ipmax and Ipmin. The state of charge is in state variable SOC, which is an alias of pIG\_y.

## Discrete

Name	Symbol	Type	Info
SWPQ	$SW_{PQ}$	Switcher	
FL1	$FL1$	Limiter	Under frequency comparer
FL2	$FL2$	Limiter	Over frequency comparer
DB_db	$db_{DB}$	DeadBand	
VL1	$VL1$	Limiter	Under voltage comparer
VL2	$VL2$	Limiter	Over voltage comparer
VLo	$VLo$	Limiter	Voltage lower limit (0.01) flag
PHL	$PHL$	Limiter	limiter for Psum in [0, pmx]
VQ1	$VQ1$	Limiter	Under voltage comparer for Q droop
VQ2	$VQ2$	Limiter	Over voltage comparer for Q droop
Ipcmd_lim	$lim_{Ipcmd}$	HardLimiter	
Iqcmd_lim	$lim_{Iqcmd}$	HardLimiter	
LTN	$LTN$	LessThan	
SOClim	$SOClim$	HardLimiter	

## Blocks

Name	Symbol	Type	Info
DB	$DB$	DeadBand1	frequency deviation deadband with gain
Ipcmd	$Ipcmd$	GainLimiter	Ip with limiter and coeff.
Iqcmd	$Iqcmd$	GainLimiter	Iq with limiter and coeff.
Ipout	$Ipout$	Lag	Output Ip filter
Iqout	$Iqout$	Lag	Output Iq filter
pIG	$pIG$	Integrator	State of charge

## Config Fields in [ESD1]

Option	Sym- bol	Value	Info	Accepted val- ues
al- low_adjust		1	allow adjusting upper or lower limits	(0, 1)
ad- just_lower		0	adjust lower limit	(0, 1)
ad- just_upper		1	adjust upper limit	(0, 1)
plim	$P_{lim}$	0	enable input power limit check bound by [0, pmx]	(0, 1)

### 3.8.3 EV1

#### Group *DG*

Electric vehicle model type 1.

Modified from ESD1 model by adding the minimum power limit  $pmn$ . Like  $pmx$ ,  $pmn$  acts on  $Psum$ , the sum of the active power references.

The limiter that uses  $pmx$  and  $pmn$  is enabled by default.

#### Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx

## Services

Name	Sym- bol	Equation	Type
pref0	$P_{ref0}$	$P_{0s}\gamma_p$	ConstService
qref0	$Q_{ref0}$	$Q_{0s}\gamma_q$	ConstService
Kft01	$K_{ft01}$	$\frac{1}{-f_{t0}+f_{t1}}$	ConstService
Kft23	$K_{ft23}$	$\frac{1}{-f_{t2}+f_{t3}}$	ConstService
Kvt01	$K_{vt01}$	$\frac{1}{-V_{t0}+V_{t1}}$	ConstService
Kvt23	$K_{vt23}$	$\frac{1}{-V_{t2}+V_{t3}}$	ConstService
Pext0	$P_{ext0}$	0	ConstService
Vcomp	$V_{comp}$	$ V e^{i\theta} + i x_c (y_{Ipout} + i y_{Iqout}) $	VarService
Vqu	$V_{qu}$	$v_1 - \frac{Q_{ref0} - q_{mn}}{dq/dv}$	ConstService
Vql	$V_{ql}$	$v_0 + \frac{-Q_{ref0} + q_{mx}}{dq/dv}$	ConstService
Ipmaxsq	$I_{pmax}^2$	$\text{FixPiecewise} \left( \left( 0, I_{alim}^2 - (y_{Iqcmd})^2 \leq 0 \right), \left( I_{alim}^2 - (y_{Iqcmd})^2, \text{True} \right) \right)$	VarService
Ip-maxsq0	$I_{pmax0}^2$	$\text{FixPiecewise} \left( \left( 0, I_{alim}^2 - \frac{Q_{ref0}^2 u^2}{V^2} \leq 0 \right), \left( I_{alim}^2 - \frac{Q_{ref0}^2 u^2}{V^2}, \text{True} \right) \right)$	ConstService
Iqmaxsq	$I_{qmax}^2$	$\text{FixPiecewise} \left( \left( 0, I_{alim}^2 - (y_{Ipcmd})^2 \leq 0 \right), \left( I_{alim}^2 - (y_{Ipcmd})^2, \text{True} \right) \right)$	VarService
Iq-maxsq0	$I_{qmax0}^2$	$\text{FixPiecewise} \left( \left( 0, I_{alim}^2 - \frac{P_{ref0}^2 u^2}{V^2} \leq 0 \right), \left( I_{alim}^2 - \frac{P_{ref0}^2 u^2}{V^2}, \text{True} \right) \right)$	ConstService

## Discrete

Name	Symbol	Type	Info
SWPQ	$SW_{PQ}$	Switcher	
FL1	$FL1$	Limiter	Under frequency comparer
FL2	$FL2$	Limiter	Over frequency comparer
DB_db	$db_{DB}$	DeadBand	
VL1	$VL1$	Limiter	Under voltage comparer
VL2	$VL2$	Limiter	Over voltage comparer
VLo	$VLo$	Limiter	Voltage lower limit (0.01) flag
PHL	$PHL$	Limiter	limiter for Psum in [pmn, pmx]
VQ1	$VQ1$	Limiter	Under voltage comparer for Q droop
VQ2	$VQ2$	Limiter	Over voltage comparer for Q droop
Ipcmd_lim	$lim_{Ipcmd}$	HardLimiter	
Iqcmd_lim	$lim_{Iqcmd}$	HardLimiter	
LTN	$LTN$	LessThan	
SOClim	$SOClim$	HardLimiter	

### Blocks

Name	Symbol	Type	Info
DB	$DB$	DeadBand1	frequency deviation deadband with gain
Ipcmd	$Ipcmd$	GainLimiter	Ip with limiter and coeff.
Iqcmd	$Iqcmd$	GainLimiter	Iq with limiter and coeff.
Ipout	$Ipout$	Lag	Output Ip filter
Iqout	$Iqout$	Lag	Output Iq filter
pIG	$pIG$	Integrator	State of charge

### Config Fields in [EV1]

Option	Sym- bol	Value	Info	Accepted val- ues
al- low_adjust		1	allow adjusting upper or lower limits	(0, 1)
ad- just_lower		0	adjust lower limit	(0, 1)
ad- just_upper		1	adjust upper limit	(0, 1)
plim	$P_{lim}$	0	enable input power limit check bound by [0, pmx]	(0, 1)

### 3.8.4 EV2

#### Group *DG*

Electric vehicle model type 2.

Derived from EV1, EV2 introduces *pcap* multiplied to *pmx*.

*Psum* will be limited to [*pmn*, *pmx* \* *pcap*].

The model does not check the signs or values of *pmn*, *pmx*, or *pcap*. The input data is required to satisfy  $pmn \leq pmx * pcap$ .

#### Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		interface bus id			mandatory
gen		static generator index			mandatory
Sn	$S_n$	device MVA rating	100	<i>MVA</i>	
fn	$f_n$	nominal frequency	60	<i>Hz</i>	
busf		Optional BusFreq measurement device idx			
xc	$x_c$	coupling reactance	0	<i>p.u.</i>	<i>z</i>
pqflag		P/Q priority for I limit; 0-Q priority, 1-P priority		<i>bool</i>	mandatory
igreg		Remote bus idx for droop response, None for local			
qmx	$q_{mx}$	Max. reactive power command	0.330	<i>pu</i>	power
qmn	$q_{mn}$	Min. reactive power command	-0.330	<i>pu</i>	power
pmx	$p_{mx}$	maximum power limit	999	<i>pu</i>	power
v0	$v_0$	Lower limit of deadband for Vdroop response	0.800	<i>pu</i>	non_zero
v1	$v_1$	Upper limit of deadband for Vdroop response	1.100	<i>pu</i>	non_zero
dqdv	$dq/dv$	Q-V droop characteristics (negative)	-1		non_zero,pow
fdbd	$f_{dbd}$	frequency deviation deadband	-0.017	<i>Hz</i>	non_positive
ddn	$D_{dn}$	Gain after f deadband	1	<i>pu (MW)/Hz</i>	non_negative,
ialim	$I_{alim}$	Apparent power limit	1.300		non_zero,non_
vt0	$V_{t0}$	Voltage tripping response curve point 0	0.880	<i>p.u.</i>	non_zero,non_
vt1	$V_{t1}$	Voltage tripping response curve point 1	0.900	<i>p.u.</i>	non_zero,non_
vt2	$V_{t2}$	Voltage tripping response curve point 2	1.100	<i>p.u.</i>	non_zero,non_
vt3	$V_{t3}$	Voltage tripping response curve point 3	1.200	<i>p.u.</i>	non_zero,non_
vrflag	$z_{VR}$	V-trip is latching (0) or self-resetting (0-1)	0		
ft0	$f_{t0}$	Frequency tripping response curve point 0	59.500	<i>Hz</i>	non_zero,non_
ft1	$f_{t1}$	Frequency tripping response curve point 1	59.700	<i>Hz</i>	non_zero,non_
ft2	$f_{t2}$	Frequency tripping response curve point 2	60.300	<i>Hz</i>	non_zero,non_
ft3	$f_{t3}$	Frequency tripping response curve point 3	60.500	<i>Hz</i>	non_zero,non_
frflag	$z_{FR}$	f-trip is latching (0) or self-resetting (0-1)	0		
tip	$T_{ip}$	Inverter active current lag time constant	0.020	<i>s</i>	non_negative
tiq	$T_{iq}$	Inverter reactive current lag time constant	0.020	<i>s</i>	non_negative

continue

Table 9 – continued from previous page

Name	Symbol	Description	Default	Unit	Properties
gammap	$\gamma_p$	Ratio of PVD1.pref0 w.r.t to that of static PV	1		
gammaq	$\gamma_q$	Ratio of PVD1.qref0 w.r.t to that of static PV	1		
recflag	$z_{rec}$	Enable flag for voltage and frequency recovery limiters	1		
Tf	$T_f$	Integrator constant for SOC model	1		
SOCmin	$SOC_{min}$	Minimum required value for SOC in limiter	0		
SOCmax	$SOC_{max}$	Maximum allowed value for SOC in limiter	1		
SOCinit	$SOC_{init}$	Initial state of charge	0.500		
En	$E_n$	Rated energy capacity	100	MWh	
EtaC	$Eta_C$	Efficiency during charging	1		
EtaD	$Eta_D$	Efficiency during discharging	1		
pmn	$p_{mn}$	minimum power limit	-999	pu	power
pcap	$p_{cap}$	power ratio multiplied to pmx in [-1, 1]	0		

## Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
Ipout_y	$y_{Ipout}$	State	State in lag transfer function		v_str
Iqout_y	$y_{Iqout}$	State	State in lag transfer function		v_str
pIG_y	$y_{pIG}$	State	Integrator output		v_str
SOC	$SOC$	AliasState	Alias for state of charge		
fHz	$f_{Hz}$	Algeb	frequency in Hz	Hz	v_str
Ffl	$F_{fl}$	Algeb	Coeff. for under frequency		v_str
Ffh	$F_{fh}$	Algeb	Coeff. for over frequency		v_str
Fdev	$f_{dev}$	Algeb	Frequency deviation	Hz	v_str
DB_y	$y_{DB}$	Algeb	Deadband type 1 output		v_str
Fvl	$F_{vl}$	Algeb	Coeff. for under voltage		v_str
Fvh	$F_{vh}$	Algeb	Coeff. for over voltage		v_str
vp	$V_p$	Algeb	Sensed positive voltage		v_str
Pext	$P_{ext}$	Algeb	External power signal (for AGC)		v_str
Pref	$P_{ref}$	Algeb	Reference power signal (for scheduling setpoint)		v_str
Psum	$P_{tot}$	Algeb	Sum of P signals		v_str
Qdrp	$Q_{drp}$	Algeb	External power signal (for AGC)		v_str
Qref	$Q_{ref}$	Algeb	Reference power signal (for scheduling setpoint)		v_str
Qsum	$Q_{tot}$	Algeb	Sum of Q signals		v_str
Ipul	$I_{p,ul}$	Algeb	Ipcmd before Ip hard limit		v_str
Iqul	$I_{q,ul}$	Algeb	Iqcmd before Iq hard limit		v_str
Ipmax	$I_{pmax}$	Algeb	Upper limit of Ip		v_str
Iqmax	$I_{qmax}$	Algeb	Upper limit of Iq		v_str
Ipcmd_x	$x_{Ipcmd}$	Algeb	Value before limiter		v_str
Ipcmd_y	$y_{Ipcmd}$	Algeb	Output after limiter and post gain		v_str
Iqcmd_x	$x_{Iqcmd}$	Algeb	Value before limiter		v_str
Iqcmd_y	$y_{Iqcmd}$	Algeb	Output after limiter and post gain		v_str
Ipmin	$I_{pmin}$	Algeb	Minimum value of Ip		v_str

plim	$P_{lim}$	0	enable input power limit check bound by [0, pmx]	(0, 1)

## 3.9 DGProtection

Protection model for DG.

Common Parameters: *u*, *name*

Available models: *DGPRCT1*, *DGPRCTExt*

### 3.9.1 DGPRCT1

Group *DGProtection*

DGPRCT1 model, follow IEEE-1547-2018. DGPRCT stands for DG protection.

A demo is provided: `examples/demonstration/1.1 demo_DGPRCT1.ipynb`

Target device (limited to DG group) *Psum* and *Qsum* will decrease to zero immediately when frequency/voltage protection flag is raised. Once the lock is released, *Psum* and *Qsum* will return to normal immediately.

DG group base model *PVD1* already has a degrading function which is used to degrade output under abnormal condition. it is recommended to turn it off by setting *recflag* = 0.

*fen* and *Ven* are protection enabling parameters. 1/0 is on/off.

*ue* is lock flag signal.

It should be noted that, the lock only lock the *fHz* (frequency read value) of DG model. The source values (which come from *BusFreq* remain unchanged.)

Protection sensors (e.g., *IAWf1*) are instances of *IntergratorAntiWindup*. All the protection sensors will be reset after *ue* returns to 0. Resetting action takes *Tres* to finish.

The model does not check the shedding points sequence. The input parameters are required to satisfy  $f_{l3} < f_{l2} < f_{l1} < f_{u1} < f_{u2} < f_{u3}$ , and  $u_{l4} < u_{l3} < u_{l2} < u_{l1} < u_{u1} < u_{u2} < u_{u3}$ .

Default settings:

Frequency (Hz):

$(f_{l3}, f_{l2}), T_{fl2}$  [(50.0, 57.5), 10s]

$(f_{l2}, f_{l1}), T_{fl1}$  [(57.5, 59.2), 300s]

$(f_{u1}, f_{u2}), T_{fu1}$  [(60.5, 61.5), 300s]

$(f_{u2}, f_{u3}), T_{fu2}$  [(61.5, 70.0), 10s]

Voltage (p.u.):

$(v_{l4}, v_{l3}), T_{vl3}$  [(0.10, 0.45), 0.16s]

$(v_{l3}, v_{l2}), T_{vl2}$  [(0.45, 0.60), 1s]

$(v_{l2}, v_{l1}), T_{vl1}$  [(0.60, 0.88), 2s]

(*vu1*, *vu2*), *Tvu1* [(1.10, 1.20), 1s]

(*vu2*, *vu3*), *Tvu2* [(1.20, 2.00), 0.16s]

adjust_upper		1	adjust upper limit	(0, 1)

### 3.9.2 DGPRCTExt

#### Group *DGProtection*

DGPRCT External model, follow IEEE-1547-2018. DGPRCT stands for DG protection.

Similar to DGPRCT1, but the measured voltage can be manipulated.

A demo is provided: examples/demonstration/1.2 demo\_DGPRCTExt.ipynb

This model can be applied to co-simulation, where you can input the external votage signal into ANDES. If no extertal value is applied, the votalge will remain as the initialized value.

Target device (limited to DG group) Psum and Qsum will decrease to zero immediately when frequency/voltage protection flag is raised. Once the lock is released, Psum and Qsum will return to normal immediately.

DG group base model PVD1 already has a degrading function which is used to degrade output under abnormal condition. it is recommended to turn it off by setting  $recflag = 0$ .

fen and Ven are protection enabling parameters. 1/0 is on/off.

ue is lock flag signal.

It should be noted that, the lock only lock the fHz (frequency read value) of DG model. The source values (which come from BusFreqf remain unchanged.)

Protection sensors (e.g., IAWf1) are instances of IntergratorAntiWindup. All the protection sensors will be reset after ue returns to 0. Resetting action takes  $Tres$  to finish.

The model does not check the shedding points sequence. The input parameters are required to satisfy  $f13 < f12 < f11 < fu1 < fu2 < fu3$ , and  $ul4 < ul3 < ul2 < ul1 < uu1 < uu2 < uu3$ .

Default settings:

Frequency (Hz):

$(f13, f12), T12 [(50.0, 57.5), 10s]$

$(f12, f11), T11 [(57.5, 59.2), 300s]$

$(fu1, fu2), Tfu1 [(60.5, 61.5), 300s]$

$(fu2, fu3), Tfu2 [(61.5, 70.0), 10s]$

Voltage (p.u.):

$(vl4, vl3), Tvl3 [(0.10, 0.45), 0.16s]$

$(vl3, vl2), Tvl2 [(0.45, 0.60), 1s]$

( $vl2$ ,  $vl1$ ),  $Tvl1$  [(0.60, 0.88), 2s]

( $vu1$ ,  $vu2$ ),  $Tvu1$  [(1.10, 1.20), 1s]

( $vu2$ ,  $vu3$ ),  $Tvu2$  [(1.20, 2.00), 0.16s]

adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.10 DynLoad

Dynamic load group.

Common Parameters: *u*, *name*

Available models: *ZIP*, *FLoad*

### 3.10.1 ZIP

Group *DynLoad*

ZIP load model (polynomial load). This model is initialized after power flow.

Please check the config of PQ to avoid double counting. If this ZIP model is in use, one should typically set  $p2p=1.0$  and  $q2q=1.0$  while leaving the others ( $p2i$ ,  $p2z$ ,  $q2i$ ,  $q2z$ , and  $pq2z$ ) as zeros. This setting allows one to impose the desired powers by the static PQ and to convert them based on the percentage specified in the ZIP.

The percentages for active power, ( $kpp$ ,  $kpi$ , and  $kpz$ ) must sum up to 100. Otherwise, initialization will fail. The same applies to the reactive power percentages.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
<i>u</i>	<i>u</i>	connection status	1	<i>bool</i>	
<i>name</i>		device name			
<i>pq</i>		idx of the PQ to replace			mandatory
<i>kpp</i>	$K_{pp}$	Percentage of active power			mandatory
<i>kpi</i>	$K_{pi}$	Percentage of active current			mandatory
<i>kpz</i>	$K_{pz}$	Percentage of conductance			mandatory
<i>kqp</i>	$K_{qp}$	Percentage of reactive power			mandatory
<i>kqi</i>	$K_{qi}$	Percentage of reactive current			mandatory
<i>kqz</i>	$K_{qz}$	Percentage of susceptance			mandatory
<i>bus</i>		retrieved bus idx	0		

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
<i>a</i>	$\theta$	ExtAlgeb			
<i>v</i>	$V$	ExtAlgeb

adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.11 Exciter

Exciter group for synchronous generators.

Common Parameters: u, name, syn

Common Variables: vout, vi

Available models: *EXDC2*, *IEEEX1*, *ESDC2A*, *EXST1*, *ESST3A*, *SEXS*, *IEEET1*, *EXAC1*, *EXAC4*, *ESST4B*, *AC8B*, *IEEET3*, *ESAC1A*, *ESST1A*

### 3.11.1 EXDC2

Group *Exciter*

EXDC2 model.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
syn		Synchronous generator idx			mandatory
TR	$T_R$	Sensing time constant	0.010	<i>p.u.</i>	
TA	$T_A$	Lag time constant in anti-windup lag	0.040	<i>p.u.</i>	
TC	$T_C$	Lead time constant in lead-lag	1	<i>p.u.</i>	
TB	$T_B$	Lag time constant in lead-lag	1	<i>p.u.</i>	
TE	$T_E$	Exciter integrator time constant	0.800	<i>p.u.</i>	
TF1	$T_{F1}$	Feedback washout time constant	1	<i>p.u.</i>	non_zero
KF1	$K_{F1}$	Feedback washout gain	0.030	<i>p.u.</i>	
KA	$K_A$	Gain in anti-windup lag TF	40	<i>p.u.</i>	
KE	$K_E$	Gain added to saturation	1	<i>p.u.</i>	
VRMAX	$V_{RMAX}$	Maximum excitation limit	7.300	<i>p.u.</i>	
VRMIN	$V_{RMIN}$	Minimum excitation limit	-7.300	<i>p.u.</i>	
E1	$E_1$	First saturation point	0	<i>p.u.</i>	
SE1	$S_{E1}$	Value at first saturation point	0	<i>p.u.</i>	
E2	$E_2$	Second saturation point	1	<i>p.u.</i>	
SE2	$S_{E2}$	Value at second saturation point	1	<i>p.u.</i>	
ug	$u_g$	Generator online status	0	<i>bool</i>	
Sn	$S_m$	Rated power from generator	0	<i>MVA</i>	
Vn	$V_m$	Rated voltage from generator	0	<i>kV</i>	
bus	$bus$	Bus idx of the generators	0		

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
vp	$V_p$	State	Voltage after saturation feedback, before speed term	<i>p.u.</i>	v_str
LS_y	$y_{LS}$	State	State in lag transfer function		v_str
LL_x	$x'_{LL}$	State	State in lead-lag		v_str
LA_y	$y_{LA}$	State	State in lag TF		v_str
W_x	$x'_W$	State	State in washout filter		v_str
omega	$\omega$	ExtState	Generator speed		
v	$E_{term}$	Algeb	Input to exciter (bus v or Eterm)		v_str
vout	$v_{out}$	Algeb	Exciter final output voltage		v_str
vref	$V_{ref}$	Algeb	Reference voltage input	<i>p.u.</i>	v_str
Se	$S_e( V_{out} )$	Algeb	saturation output		v_str
vi	$V_i$	Algeb	Total input voltages	<i>p.u.</i>	v_str
LL_y	$y_{LL}$	Algeb	Output of lead-lag		v_str
W_y	$y_W$	Algeb	Output of washout filter		v_str
vf	$v_f$	ExtAlgeb	Excitation field voltage to generator		
Xad-Ifd	$X_{ad}I_{fd}$	ExtAlgeb	Armature excitation current		
a	$\theta$	ExtAlgeb	Bus voltage phase angle		
vbus	$V$	ExtAlgeb	Bus voltage magnitude		

## Variable Initialization Equations

Name	Symbol	Type	Initial Value
vp	$V_p$	State	$v_{f0}$
LS_y	$y_{LS}$	State	$1.0E_{term}$

adjust_upper		1	adjust upper limit	(0, 1)

### 3.11.3 ESDC2A

Group *Exciter*

ESDC2A model.

This model is implemented as described in the PSS/E manual, except that the HVGate is not in use. Due to the HVGate and saturation function, the results are close to but different from TSAT.

Parameters

Name	Sym- bol	Description	De- fault	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
syn		Synchronous generator idx			mandatory
TR	$T_R$	Sensing time constant	0.010	<i>p.u.</i>	
KA	$K_A$	Regulator gain	80		
TA	$T_A$	Lag time constant in regulator	0.040	<i>p.u.</i>	
TB	$T_B$	Lag time constant in lead-lag	1	<i>p.u.</i>	
TC	$T_C$	Lead time constant in lead-lag	1	<i>p.u.</i>	
VR- MAX	$V_{RMAX}$	Max. exc. limit (0-unlimited)	7.300	<i>p.u.</i>	
VRMIN	$V_{RMIN}$	Min. excitation limit	-7.300	<i>p.u.</i>	
KE	$K_E$	Saturation feedback gain	1	<i>p.u.</i>	
TE	$T_E$	Integrator time constant	0.800	<i>p.u.</i>	
KF	$K_F$	Feedback gain	0.100		
TF1	$T_{F1}$	Feedback washout time constant	1	<i>p.u.</i>	non_zero,non_negative
Switch	$S_w$	Switch that PSS/E did not implement	0	<i>bool</i>	
E1	$E_1$	First saturation point	0	<i>p.u.</i>

## 3.12 Experimental

Experimental group

Common Parameters: u, name

## 3.13 FreqMeasurement

Frequency measurements.

Common Parameters: u, name

Common Variables: f

Available models: *BusFreq*, *BusROCOF*

### 3.13.1 BusFreq

Group *FreqMeasurement*

Bus frequency measurement. Outputs frequency in per unit value.

The bus frequency output variable is  $f$ . The frequency deviation variable is  $WO_y$ .

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		bus idx			mandatory
Tf	$T_f$	input digital filter time const	0.020	<i>sec</i>	
Tw	$T_w$	washout time const	0.020	<i>sec</i>	
fn	$f_n$	nominal frequency	60	<i>Hz</i>	

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
L_y	$y_L$	State	State in lag transfer function		v_str
WO_x	$x'_{WO}$	State	State in washout filter		v_str
WO_y	$y_{WO}$	Algeb	frequency deviation	<i>p.u. (Hz)</i>	v_str
f	$f$	Algeb	frequency output	<i>p.u. (Hz)</i>	v_str
a	$\theta$	ExtAlgeb			
v	$V$	ExtAlgeb			

## Variable Initialization Equations

Name	Symbol	Type	Initial Value
L_y	$y_L$	State	$\theta - \theta_0$
WO_x	$x'_{WO}$	State	$y_L$
WO_y	$y_{WO}$	Algeb	0
f	$f$	Algeb	1
a	$\theta$	ExtAlgeb	
v	$V$	ExtAlgeb	

## Differential Equations

Name	Symbol	Type	RHS of Equation "T x' = f(x, y)"	T (LHS)
L_y	$y_L$	State	$\theta - \theta_0 - y_L$	$T_f$
WO_x	$x'_{WO}$	State	$-x'_{WO} + y_L$	$T_w$

## Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
WO_y	$y_{WO}$	Algeb	$1/\omega_n (-x'_{WO} + y_L) - T_w y_{WO}$
f	$f$	Algeb	$-f + y_{WO} + 1$
a	$\theta$	ExtAlgeb	0
v	$V$	ExtAlgeb	0

## Services

Name	Symbol	Equation	Type
iwn	$1/\omega_n$	$\frac{u}{2\pi f_n}$	ConstService

## Blocks

Name	Symbol	Type	Info
L	$L$	Lag	digital filter
WO	$WO$	Washout	angle washout

Config Fields in [BusFreq]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

### 3.13.2 BusROCOF

Group *FreqMeasurement*

Bus frequency and ROCOF measurement.

The ROCOF output variable is  $Wf\_y$ .

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		bus idx			mandatory
Tf	$T_f$	input digital filter time const	0.020	<i>sec</i>	
Tw	$T_w$	washout time const	0.020	<i>sec</i>	
fn	$f_n$	nominal frequency	60	<i>Hz</i>	
Tr	$T_r$	frequency washout time constant	0.100		

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
L_y	$y_L$	State	State in lag transfer function		v_str

## Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
WO_y	$y_{WO}$	Algeb	$1/\omega_n (-x'_{WO} + y_L) - T_w y_{WO}$
f	$f$	Algeb	$-f + y_{WO} + 1$
Wf_y	$y_{Wf}$	Algeb	$-T_r y_{Wf} + f - x'_{Wf}$
a	$\theta$	ExtAlgeb	0
v	$V$	ExtAlgeb	0

## Services

Name	Symbol	Equation	Type
iwn	$1/\omega_n$	$\frac{u}{2\pi f_n}$	ConstService

## Blocks

Name	Symbol	Type	Info
L	$L$	Lag	digital filter
WO	$WO$	Washout	angle washout
Wf	$Wf$	Washout	frequency washout yielding ROCOF

## Config Fields in [BusROCOF]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.14 Information

Group for information container models.

Available models: *Summary*

### 3.14.1 Summary

Group *Information*

Class for storing system summary. Can be used for random information or notes.

Parameters

Name	Symbol	Description	Default	Unit	Properties
field		field name			
comment		information, comment, or anything			
comment2		comment field 2			
comment3		comment field 3			
comment4		comment field 4			

Config Fields in [Summary]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.15 Motor

Induction Motor group

Common Parameters: u, name

Available models: *Motor3*, *Motor5*

### 3.15.1 Motor3

Group *Motor*

Third-order induction motor model.

See "Power System Modelling and Scripting" by F. Milano.

To simulate motor startup, set the motor status u to 0 and use a `Toggler` to control the model.

## Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		interface bus id			mandatory
Sn	$S_n$	Power rating	100		
Vn	$V_n$	AC voltage rating	110		
fn	$f$	rated frequency	60		
rs	$r_s$	rotor resistance	0.010		non_zero,z
xs	$x_s$	rotor reactance	0.150		non_zero,z
rr1	$r_{R1}$	1st cage rotor resistance	0.050		non_zero,z
xr1	$x_{R1}$	1st cage rotor reactance	0.150		non_zero,z
rr2	$r_{R2}$	2st cage rotor resistance	0.001		non_zero,z
xr2	$x_{R2}$	2st cage rotor reactance	0.040		non_zero,z
xm	$x_m$	magnetization reactance	5		non_zero,z
Hm	$H_m$	Inertia constant	3	<i>kWs/KVA</i>	power
c1	$c_1$	1st coeff. of Tm(w)	0.100		
c2	$c_2$	2nd coeff. of Tm(w)	0.020		
c3	$c_3$	3rd coeff. of Tm(w)	0.020		
zb	$z_b$	Allow working as brake	1		

## Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties

## 3.16 PSS

Power system stabilizer group.

Common Parameters: u, name

Common Variables: vsout

Available models: *IEEEST*, *ST2CUT*

### 3.16.1 IEEEST

Group *PSS*

IEEEST stabilizer model. Automatically adds frequency measurement devices if not provided.

Input signals (MODE):

1 - Rotor speed deviation (p.u.), 2 - Bus frequency deviation (\*) (p.u.), 3 - Generator P electrical in Gen MVABase (p.u.), 4 - Generator accelerating power (p.u.), 5 - Bus voltage (p.u.), 6 - Derivative of p.u. bus voltage.

(\*) Due to the frequency measurement implementation difference, mode 2 is likely to yield different results across software.

Blocks are named *F1*, *F2*, *LL1*, *LL2* and *WO* in sequence. Two limiters are named *VLIM* and *OLIM* in sequence.

## Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
avr		Exciter idx			mandatory
MODE		Input signal			mandatory
busr		Optional remote bus idx			
busf		BusFreq idx for mode 2

## 3.16.2 ST2CUT

Group *PSS*

ST2CUT stabilizer model. Automatically adds frequency measurement devices if not provided.

Input signals (MODE and MODE2):

0 - Disable input signal 1 (s1) - Rotor speed deviation (p.u.), 2 (s2) - Bus frequency deviation (\*) (p.u.), 3 (s3) - Generator P electrical in Gen MVABase (p.u.), 4 (s4) - Generator accelerating power (p.u.), 5 (s5) - Bus voltage (p.u.), 6 (s6) - Derivative of p.u. bus voltage.

(\*) Due to the frequency measurement implementation difference, mode 2 is likely to yield different results across software.

Blocks are named *LL1*, *LL2*, *LL3*, *LL4* in sequence. Two limiters are named *VSS\_lim* and *OLIM* in sequence.

## Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
avr		Exciter idx			mandatory
MODE		Input signal 1			mandatory
busr		Remote bus 1			
busf		BusFreq idx for signal 1 mode 2			
MODE2		Input signal 2			
busr2		Remote bus 2			
busf2		BusFreq idx for signal 2 mode 2			
K1	$K_1$	Transducer 1 gain	1		
K2	$K_2$	Transducer 2 gain	1		
T1	$T_1$	Transducer 1 time const.	1		
T2	$T_2$	Transducer 2 time const.	1		
T3	$T_3$	Washout int. time const.	1		
T4	$T_4$	Washout delay time const.	0.200		
T5	$T_5$	Leadlag 1 time const. (1)	1		
T6	$T_6$	Leadlag 1 time const. (2)	0.500		
T7	$T_7$	Leadlag 2 time const. (1)	1		
T8	$T_8$	Leadlag 2 time const. (2)	1		
T9	$T_9$	Leadlag 3 time const. (1)	1		
T10	$T_{10}$	Leadlag 3 time const. (2)	0.200		
LSMAX	$L_{SMAX}$	Max. output limit	0.300		
LSMIN	$L_{SMIN}$	Min. output limit	-0.300		
VCU	$V_{CU}$	Upper enabling bus voltage	999	<i>p.u.</i>	
VCL	$V_{CL}$	Upper enabling bus voltage	-999	<i>p.u.</i>	
syn		Retrieved generator idx	0		
bus		Retrieved bus idx			
Sn	$S_n$	Generator power base	0		

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
L1_y	$y_{L1}$	State	State in lag transfer function		v_str
L2_y	$y_{L2}$	State	State in lag transfer function		v_str

v2	$V$	ExtAl- geb	0
f2	$f_2$	ExtAl- geb	0

## Services

Name	Symbol	Equation	Type
VOU	$VOU$	$VCUr + V_0$	ConstService
VOL	$VOL$	$VCLr + V_0$	ConstService

## Discrete

Name	Symbol	Type	Info
dv	$dv$	Derivative	
dv2	$dv2$	Derivative	
SW	$SW$	Switcher	
SW2	$SW2$	Switcher	
WO_LT	$LT_{WO}$	LessThan	
LL1_LT1	$LT_{LL1}$	LessThan	
LL1_LT2	$LT_{LL1}$	LessThan	
LL2_LT1	$LT_{LL2}$	LessThan	
LL2_LT2	$LT_{LL2}$	LessThan	
LL3_LT1	$LT_{LL3}$	LessThan	
LL3_LT2	$LT_{LL3}$	LessThan	
VSS_lim	$lim_{VSS}$	HardLimiter	
OLIM	$OLIM$	Limiter	output limiter

## Blocks

Name	Symbol	Type	Info
L1	$L1$	Lag	Transducer 1
L2	$L2$	Lag	Transducer 2
WO	$WO$	WashoutOrLag	
LL1	$LL1$	LeadLag	
LL2	$LL2$	LeadLag	
LL3	$LL3$	LeadLag	
VSS	$VSS$	GainLimiter	

## Config Fields in [ST2CUT]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)
freq_model		BusFreq	default freq. measurement model	('BusFreq',)

## 3.17 PhasorMeasurement

Phasor measurements

Common Parameters: u, name

Common Variables: am, vm

Available models: *PMU*

### 3.17.1 PMU

Group *PhasorMeasurement*

Simple phasor measurement unit model.

This model tracks the bus voltage magnitude and phase angle, each using a low-pass filter.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		bus idx			mandatory
Ta	$T_a$	angle filter time constant	0.100		
Tv	$T_v$	voltage filter time constant	0.100		

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
am	$\theta_m$	State	phase angle measurement	<i>rad.</i>	v_str
vm	$V_m$	State	voltage magnitude measurement	<i>p.u.(kV)</i>	v_str
a	$\theta$	ExtAlgeb	Bus voltage phase angle		
v	$V$	ExtAlgeb	Bus voltage magnitude		

Variable Initialization Equations

Name	Symbol	Type	Initial Value
am	$\theta_m$	State	$\theta$
vm	$V_m$	State	$V$
a	$\theta$	ExtAlgeb	
v	$V$	ExtAlgeb	

Differential Equations

Name	Symbol	Type	RHS of Equation " $\dot{x} = f(x, y)$ "	T (LHS)
am	$\theta_m$	State	$\dot{\theta} - \theta_m$	$T_a$
vm	$V_m$	State	$\dot{V} - V_m$	$T_v$

Algebraic Equations

Name	Symbol	Type	RHS of Equation " $0 = g(x, y)$ "
a	$\theta$	ExtAlgeb	0
v	$V$	ExtAlgeb	0

Config Fields in [PMU]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.18 RenAerodynamics

Renewable aerodynamics group.

Common Parameters: u, name, rego

Common Variables: theta

Available models: *WTARA1*, *WTARV1*

### 3.18.1 WTARA1

Group *RenAerodynamics*

Wind turbine aerodynamics model (no wind speed details).

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
rego		Renewable governor idx			mandatory
Ka	$K_a$	Aerodynamics gain	1	<i>p.u./deg.</i>	non_negative
theta0	$\theta_0$	Initial pitch angle	0	<i>deg.</i>	

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
theta	$\theta$	Algeb	Pitch angle	<i>rad</i>	v_str
Pmg	$Pmg$	ExtAlgeb			

Variable Initialization Equations

Name	Symbol	Type	Initial Value
theta	$\theta$	Algeb	$\theta_{0r}$
Pmg	$Pmg$	ExtAlgeb	

Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
theta	$\theta$	Algeb	$-\theta + \theta_{0r}$
Pmg	$Pmg$	ExtAlgeb	$-\theta (\theta - \theta_0)$

Services

Name	Symbol	Equation	Type
theta0r	$\theta_{0r}$	$\frac{\pi\theta_0}{180}$	ConstService

Config Fields in [WTARA1]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

### 3.18.2 WTARV1

Group *RenAerodynamics*

Wind turbine aerodynamics model with wind velocity details.

Work is in progress.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
rego		Renewable governor idx			mandatory
nblade		number of blades	3		
ngen		number of wind generator units	50		
npole		number of poles in generator	4		
R		rotor radius	30	<i>m</i>	
ngb		gear box ratio	5		
rho		air density	1.200	<i>kg/m3</i>	
Sn	$S_n$		0		

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
theta	$\theta$	Algeb	Pitch angle	<i>rad</i>	
Pmg	$Pmg$	ExtAlgeb			

## Variable Initialization Equations

Name	Symbol	Type	Initial Value
theta	$\theta$	Algeb	
Pmg	$P_{mg}$	ExtAlgeb	

## Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
theta	$\theta$	Algeb	0
Pmg	$P_{mg}$	ExtAlgeb	0

## Config Fields in [WTARV1]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.19 RenExciter

Renewable electrical control (exciter) group.

Common Parameters: u, name, reg

Common Variables: Pref, Qref, wg, Pord

Available models: *REECA1*, *REECA1E*, *REECA1G*

### 3.19.1 REECA1

Group *RenExciter*

Renewable energy electrical control.

There are two user-defined voltages:  $V_{ref0}$  and  $V_{ref1}$ .

- The difference between the initial bus voltage and  $V_{ref0}$  should be within the voltage dead-bands  $dbd1$  and  $dbd2$ .
- If  $VFLAG=0$ , the input to the second PI controller will be  $V_{ref1}$ .

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	

continues on next page

Table 16 – continued from previous page

Name	Symbol	Description	Default	Unit	Properties
name		device name			
reg		Renewable generator idx			mandatory
busr		Optional remote bus for voltage control			
PFLAG		Power factor control flag; 1-PF control, 0-Q control		<i>bool</i>	mandatory
VFLAG		Voltage control flag; 1-Q control, 0-V control		<i>bool</i>	mandatory
QFLAG		Q control flag; 1-V or Q control, 0-const. PF or Q		<i>bool</i>	mandatory
PFLAG		P speed-dependency flag; 1-has speed dep., 0-no dep.		<i>bool</i>	mandatory
PQFLAG		P/Q priority flag for I limit; 0-Q priority, 1-P priority		<i>bool</i>	mandatory
Vdip	$V_{dip}$	Low V threshold to activate Iqinj logic	0.800	<i>p.u.</i>	
Vup	$V_{up}$	V threshold above which to activate Iqinj logic	1.200	<i>p.u.</i>	
Trv	$T_{rv}$	Voltage filter time constant	0.020		
dbd1	$d_{bd1}$	Lower bound of the voltage deadband ( $\leq 0$ )	-0.020		
dbd2	$d_{bd2}$	Upper bound of the voltage deadband ( $\geq 0$ )	0.020		
Kqv	$K_{qv}$	Gain to compute Iqinj from V error	1		
Iqh1	$I_{qh1}$	Upper limit on Iqinj	999		
Iql1	$I_{ql1}$	Lower limit on Iqinj	-999		
Vref0	$V_{ref0}$	User defined Vref (if 0, use initial bus V)	1		
Iqfrz	$I_{qfrz}$	Hold Iqinj at the value for Thld ( $>0$ ) seconds following a Vdip	0		
Thld	$T_{hld}$	Time for which Iqinj is held. Hold at Iqinj if $>0$ ; hold at State 1 if $<0$	0	<i>s</i>	
Thld2	$T_{hld2}$	Time for which IPMAX is held after voltage dip ends	0	<i>s</i>	
Tp	$T_p$	Filter time constant for Pe	0.020	<i>s</i>	
QMax	$Q_{max}$	Upper limit for reactive power regulator	999		
QMin	$Q_{min}$	Lower limit for reactive power regulator	-999		
VMAX	$V_{max}$	Upper limit for voltage control	999		
VMIN	$V_{min}$	Lower limit for voltage control	-999		
Kqp	$K_{qp}$	Proportional gain for reactive power error	1		
Kqi	$K_{qi}$	Integral gain for reactive power error	0.100		
Kvp	$K_{vp}$	Proportional gain for voltage error	1		
Kvi	$K_{vi}$	Integral gain for voltage error	0.100		
Vref1	$V_{ref1}$	Voltage ref. if VFLAG=0	1		non_zero
Tiq	$T_{iq}$	Filter time constant for Iq	0.020		
dPmax	$dP_{max}$	Power reference max. ramp rate ( $>0$ )	999		
dPmin	$dP_{min}$	Power reference min. ramp rate ( $<0$ )	-999		
PMAX	$P_{max}$	Max. active power limit $> 0$	999		
PMIN	$P_{min}$	Min. active power limit	0		
Imax	$I_{max}$	Max. apparent current limit	999		current
Tpord	$T_{pord}$	Filter time constant for power setpoint	0.020		
Vq1	$V_{q1}$	Reactive power V-I pair (point 1), voltage	0.200		
Iq1	$I_{q1}$	Reactive power V-I pair (point 1), current	2		current
Vq2	$V_{q2}$	Reactive power V-I pair (point 2), voltage	0.400		
Iq2	$I_{q2}$	Reactive power V-I pair (point 2), current	4		current
Vq3	$V_{q3}$	Reactive power V-I pair (point 3), voltage	0.800		
Iq3	$I_{q3}$	Reactive power V-I pair (point 3), current	8		current

## Discrete

Name	Symbol	Type	Info
SWPF	$SW_{PF}$	Switcher	
SWV	$SW_V$	Switcher	
SWQ	$SW_V$	Switcher	
SWP	$SW_P$	Switcher	
SWPQ	$SW_{PQ}$	Switcher	
zp	$zp$	IsEqual	
Vcmp	$V_{cmp}$	Limiter	Voltage dip comparator
VLower	$V_{Lower}$	Limiter	Limiter for lower voltage cap
PFlim	$P_{Flim}$	Limiter	
PIQ_lim	$lim_{PIQ}$	HardLimiter	
Vsel_lim	$lim_{Vsel}$	HardLimiter	
dbV_db	$db_{dbV}$	DeadBand	
pfilt_lim	$lim_{P_{filt}}$	RateLimiter	Rate limiter in Lag
s5_lim	$lim_{s5}$	AntiWindup	Limiter in Lag
PIV_lim	$lim_{PIV}$	HardLimiter	
IpHL_lim	$lim_{IpHL}$	HardLimiter	
IqHL_lim	$lim_{IqHL}$	HardLimiter	

## Blocks

Name	Symbol	Type	Info
s0	$s_0$	Lag	Voltage filter
S1	$S_1$	Lag	Pe filter
PIQ	$PIQ$	PITrackAWFreeze	
Vsel	$V_{sel}$	GainLimiter	Selection output of VFLAG
s4	$s_4$	LagFreeze	Filter for calculated voltage with freeze
dbV	$dbV$	DeadBand1	Deadband for voltage error (ref0)
pfilt	$P_{filt}$	LagRate	Active power filter with rate limits
s5	$s_5$	LagAWFreeze	
VDL1	$V_{DL1}$	Piecewise	Piecewise linear characteristics of Vq-Iq
VDL2	$V_{DL2}$	Piecewise	Piecewise linear characteristics of Vp-Ip
PIV	$PIV$	PITrackAWFreeze	
IpHL	$I_{pHL}$	GainLimiter	
IqHL	$I_{qHL}$	GainLimiter	

## Config Fields in [REECA1]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)
kqs	$K_{qs}$	2	Q PI controller tracking gain	
kvs	$K_{vs}$	2	Voltage PI controller tracking gain	
tpfilt	$T_{pfilt}$	0.020	Time const. for Pref filter	

## 3.19.2 REECA1E

Group *RenExciter*

REGCA1 with inertia emulation and primary frequency droop. Measurements are based on frequency measurement model.

Bus ROCOF obtained from BusROCOF devices.

## Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
reg		Renewable generator idx			mandatory
busr		Optional remote bus for voltage control			
PFFLAG		Power factor control flag; 1-PF control, 0-Q control		<i>bool</i>	mandatory

continues on next page

Table 21 – continued from previous page

Name	Symbol	Description	Default	Unit	Properties
VFLAG		Voltage control flag; 1-Q control, 0-V control		<i>bool</i>	mandatory
QFLAG		Q control flag; 1-V or Q control, 0-const. PF or Q		<i>bool</i>	mandatory
PFLAG		P speed-dependency flag; 1-has speed dep., 0-no dep.		<i>bool</i>	mandatory
PQFLAG		P/Q priority flag for I limit; 0-Q priority, 1-P priority		<i>bool</i>	mandatory
Vdip	$V_{dip}$	Low V threshold to activate Iqinj logic	0.800	<i>p.u.</i>	
Vup	$V_{up}$	V threshold above which to activate Iqinj logic	1.200	<i>p.u.</i>	
Trv	$T_{rv}$	Voltage filter time constant	0.020		
dbd1	$d_{bd1}$	Lower bound of the voltage deadband ( $\leq 0$ )	-0.020		
dbd2	$d_{bd2}$	Upper bound of the voltage deadband ( $\geq 0$ )	0.020		
Kqv	$K_{qv}$	Gain to compute Iqinj from V error	1		
Iqh1	$I_{qh1}$	Upper limit on Iqinj	999		
Iql1	$I_{ql1}$	Lower limit on Iqinj	-999		
Vref0	$V_{ref0}$	User defined Vref (if 0, use initial bus V)	1		
Iqfrz	$I_{qfrz}$	Hold Iqinj at the value for Thld ( $>0$ ) seconds following a Vdip	0		
Thld	$T_{hld}$	Time for which Iqinj is held. Hold at Iqinj if $>0$ ; hold at State 1 if $<0$	0	<i>s</i>	
Thld2	$T_{hld2}$	Time for which IPMAX is held after voltage dip ends	0	<i>s</i>	
Tp	$T_p$	Filter time constant for Pe	0.020	<i>s</i>	
QMax	$Q_{max}$	Upper limit for reactive power regulator	999		
QMin	$Q_{min}$	Lower limit for reactive power regulator	-999		
VMAX	$V_{max}$	Upper limit for voltage control	999		
VMIN	$V_{min}$	Lower limit for voltage control	-999		
Kqp	$K_{qp}$	Proportional gain for reactive power error	1		
Kqi	$K_{qi}$	Integral gain for reactive power error	0.100		
Kvp	$K_{vp}$	Proportional gain for voltage error	1		
Kvi	$K_{vi}$	Integral gain for voltage error	0.100		
Vref1	$V_{ref1}$	Voltage ref. if VFLAG=0	1		non_zero
Tiq	$T_{iq}$	Filter time constant for Iq	0.020		
dPmax	$dP_{max}$	Power reference max. ramp rate ( $>0$ )	999		
dPmin	$dP_{min}$	Power reference min. ramp rate ( $<0$ )	-999		
PMAX	$P_{max}$	Max. active power limit $> 0$	999		
PMIN	$P_{min}$	Min. active power limit	0		
Imax	$I_{max}$	Max. apparent current limit	999		current
Tpord	$T_{pord}$	Filter time constant for power setpoint	0.020		
Vq1	$V_{q1}$	Reactive power V-I pair (point 1), voltage	0.200		
Iq1	$I_{q1}$	Reactive power V-I pair (point 1), current	2		current
Vq2	$V_{q2}$	Reactive power V-I pair (point 2), voltage	0.400		
Iq2	$I_{q2}$	Reactive power V-I pair (point 2), current	4		current
Vq3	$V_{q3}$	Reactive power V-I pair (point 3), voltage	0.800		
Iq3	$I_{q3}$	Reactive power V-I pair (point 3), current	8		current
Vq4	$V_{q4}$	Reactive power V-I pair (point 4), voltage	1		
Iq4	$I_{q4}$	Reactive power V-I pair (point 4), current	10		current
Vp1	$V_{p1}$	Active power V-I pair (point 1), voltage	0.200		
Ip1	$I_{p1}$	Active power V-I pair (point 1), current	2		current

continues on next page

Table 21 – continued from previous page

Name	Symbol	Description	Default	Unit	Properties
Vp2	$V_{p2}$	Active power V-I pair (point 2), voltage	0.400		
Ip2	$I_{p2}$	Active power V-I pair (point 2), current	4		current
Vp3	$V_{p3}$	Active power V-I pair (point 3), voltage	0.800		
Ip3	$I_{p3}$	Active power V-I pair (point 3), current	8		current
Vp4	$V_{p4}$	Active power V-I pair (point 4), voltage	1		
Ip4	$I_{p4}$	Active power V-I pair (point 4), current	12		current
Kf	$K_{df}$	gain for frequency deviation	0		
Kdf	$K_{df}$	gain for rate-of-change of frequency	0		
busroc		Optional BusROCOF device idx

## Blocks

Name	Symbol	Type	Info
s0	$s0$	Lag	Voltage filter
S1	$S_1$	Lag	Pe filter
PIQ	$PIQ$	PITrackAWFreeze	
Vsel	$V_{sel}$	GainLimiter	Selection output of VFLAG
s4	$s_4$	LagFreeze	Filter for calculated voltage with freeze
dbV	$dbV$	DeadBand1	Deadband for voltage error (ref0)
pfilt	$P_{filt}$	LagRate	Active power filter with rate limits
s5	$s_5$	LagAWFreeze	
VDL1	$V_{DL1}$	Piecewise	Piecewise linear characteristics of Vq-Iq
VDL2	$V_{DL2}$	Piecewise	Piecewise linear characteristics of Vp-Ip
PIV	$PIV$	PITrackAWFreeze	
IpHL	$IpHL$	GainLimiter	
IqHL	$IqHL$	GainLimiter	

## Config Fields in [REECA1E]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)
kqs	$K_{qs}$	2	Q PI controller tracking gain	
kvs	$K_{vs}$	2	Voltage PI controller tracking gain	
tpfilt	$T_{pfilt}$	0.020	Time const. for Pref filter	

### 3.19.3 REECA1G

Group *RenExciter*

REECA1G is a variant of REECA1E.

REECA1G uses speed from synchronous generators.

The application of this model is limited because it is uncommon to connect a SynGen on the same bus as a RenGen.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
reg		Renewable generator idx			mandatory
busr		Optional remote bus for voltage control			
PFLAG		Power factor control flag; 1-PF control, 0-Q control		<i>bool</i>	mandatory
VFLAG		Voltage control flag; 1-Q control, 0-V control		<i>bool</i>	mandatory
QFLAG		Q control flag; 1-V or Q control, 0-const. PF or Q		<i>bool</i>	mandatory
PFLAG		P speed-dependency flag; 1-has speed dep., 0-no dep.		<i>bool</i>	mandatory
PQFLAG		P/Q priority flag for I limit; 0-Q priority, 1-P priority		<i>bool</i>	mandatory
Vdip	$V_{dip}$	Low V threshold to activate Iqinj logic	0.800	<i>p.u.</i>	
Vup	$V_{up}$	V threshold above which to activate Iqinj logic	1.200	<i>p.u.</i>	
Trv	$T_{rv}$	Voltage filter time constant	0.020		
dbd1	$dbd1$	Lower bound of the voltage deadband ( $\leq 0$ )	-0.020		
dbd2	$dbd2$	Upper bound of the voltage deadband ( $\geq 0$ )	0.020		
Kqv	$K_{qv}$	Gain to compute Iqinj from V error	1		
Iqh1	$I_{qh1}$	Upper limit on Iqinj	999		
Iql1	$I_{ql1}$	Lower limit on Iqinj	-999		
Vref0	$V_{ref0}$	User defined Vref (if 0, use initial bus V)	1		
Iqfrz	$I_{qfrz}$	Hold Iqinj at the value for Thld ( $>0$ ) seconds following a Vdip	0		
Thld	$T_{hld}$	Time for which Iqinj is held. Hold at Iqinj if $>0$ ; hold at State 1 if $<0$	0	<i>s</i>	
Thld2	$T_{hld2}$	Time for which IPMAX is held after voltage dip ends	0	<i>s</i>	
Tp	$T_p$	Filter time constant for Pe	0.020	<i>s</i>	
QMax	$Q_{max}$	Upper limit for reactive power regulator	999		
QMin	$Q_{min}$	Lower limit for reactive power regulator	-999		
VMAX	$V_{max}$	Upper limit for voltage control	999		
VMIN	$V_{min}$	Lower limit for voltage control	-999		
Kqp	$K_{qp}$	Proportional gain for reactive power error	1		
Kqi	$K_{qi}$	Integral gain for reactive power error	0.100		
Kvp	$K_{vp}$	Proportional gain for voltage error	1

## Discrete

Name	Symbol	Type	Info
SWPF	$SW_{PF}$	Switcher	
SWV	$SW_V$	Switcher	
SWQ	$SW_V$	Switcher	
SWP	$SW_P$	Switcher	
SWPQ	$SW_{PQ}$	Switcher	
zp	$zp$	IsEqual	
Vcmp	$V_{cmp}$	Limiter	Voltage dip comparator
VLower	$V_{Lower}$	Limiter	Limiter for lower voltage cap
PFlim	$P_{Flim}$	Limiter	
PIQ_lim	$lim_{PIQ}$	HardLimiter	
Vsel_lim	$lim_{V_{sel}}$	HardLimiter	
dbV_db	$db_{dbV}$	DeadBand	
pfilt_lim	$lim_{P_{filt}}$	RateLimiter	Rate limiter in Lag
s5_lim	$lim_{s5}$	AntiWindup	Limiter in Lag
PIV_lim	$lim_{PIV}$	HardLimiter	
IpHL_lim	$lim_{IpHL}$	HardLimiter	
IqHL_lim	$lim_{IqHL}$	HardLimiter	

### Blocks

Name	Symbol	Type	Info
s0	$s0$	Lag	Voltage filter
S1	$S_1$	Lag	Pe filter
PIQ	$PIQ$	PITrackAWFreeze	
Vsel	$V_{sel}$	GainLimiter	Selection output of VFLAG
s4	$s_4$	LagFreeze	Filter for calculated voltage with freeze
dbV	$dbV$	DeadBand1	Deadband for voltage error (ref0)
pfilt	$P_{filt}$	LagRate	Active power filter with rate limits
s5	$s_5$	LagAWFreeze	
VDL1	$V_{DL1}$	Piecewise	Piecewise linear characteristics of Vq-Iq
VDL2	$V_{DL2}$	Piecewise	Piecewise linear characteristics of Vp-Ip
PIV	$PIV$	PITrackAWFreeze	
IpHL	$IpHL$	GainLimiter	
IqHL	$IqHL$	GainLimiter	

### Config Fields in [REECA1G]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)
kqs	$K_{qs}$	2	Q PI controller tracking gain	
kvs	$K_{vs}$	2	Voltage PI controller tracking gain	
tpfilt	$T_{pfilt}$	0.020	Time const. for Pref filter	

## 3.20 RenGen

Renewable generator (converter) group.

Common Parameters: u, name, bus, gen, Sn

Common Variables: Pe, Qe

Available models: *REGCA1*, *REGCV1*, *REGCV2*

### 3.20.1 REGCA1

Group *RenGen*

Renewable energy generator model type A.

Implements REGCA1 in PSS/E, or REGC\_A in PSLF.

Volim is the voltage limit for high voltage reactive current management, which should be large than static bus voltage ( $\text{Volim} > v$ ), or initialization error will occur.

Parameters

Name	Sym- bol	Description	De- fault	Unit	Proper- ties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		interface bus id			manda- tory
gen		static generator index			manda- tory
Sn	$S_n$	Model MVA base	100	<i>MVA</i>	
Tg	$T_g$	converter time const.	0.100	<i>s</i>	
Rrpwr	$R_{rpwr}$	Low voltage power logic (LVPL) ramp limit	10	<i>p.u.</i>	
Brkpt	$B_{rkpt}$	LVPL characteristic voltage 2	1	<i>p.u.</i>	
Zerox	$Z_{erox}$	LVPL characteristic voltage 1	0.500	<i>p.u.</i>	
Lv- plsw	$z_{Lvplsw}$	Low volt. P logic: 1-enable, 0-disable	1	<i>bool</i>	
Lvpl1	$L_{vpl1}$	LVPL gain	1	<i>p.u.</i>	
Volim	$V_{olim}$	Voltage lim for high volt. reactive current mgnt.	1.200	<i>p.u.</i>	
Lvpnt1	$L_{vpnt1}$	High volt. point for low volt. active current mgnt.	0.800	<i>p.u.</i>	
Lvpnt0	$L_{vpnt0}$	Low volt. point for low volt. active current mgnt.	0.400	<i>p.u.</i>	
Iolim	$I_{olim}$	lower current limit for high volt. reactive current mgnt.	- 1.500	<i>p.u. (mach base)</i>	current
Tfltr	$T_{fltr}$	Voltage filter T const for low volt. active current mgnt.	0.100	<i>s</i>	
Khv	$K_{hv}$	Overvolt. compensation gain in high volt. reactive current mgnt.	0.700		
Iqr- max	$I_{qrmax}$	Upper limit on the ROC for reactive current	1	<i>p.u.</i>	current
Iqr- min	$I_{qrmin}$	Lower limit on the ROC for reactive current	-1	<i>p.u.</i>	current
Accel	$A_{ccel}$	Acceleration factor	0		
gammap	$\gamma_P$	P ratio of linked static gen	1		
gam- maq	$\gamma_Q$	Q ratio of linked static gen	1		
ra	$r_a$		0		
xs	$x_s$		0		

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
S1_y	$y_{S_1}$	State	State in lag TF		v_str
S2_y	$y_{S_2}$	State	State in lag transfer function		v_str
S0_y	$y_{S_0}$	State	State in lag TF		v_str

## Blocks

Name	Symbol	Type	Info
LVG	$L_{VG}$	Piecewise	Ip gain during low voltage
S1	$S_1$	LagAntiWindupRate	Iqcmd delay
S2	$S_2$	Lag	Voltage filter with no anti-windup
LVPL	$L_{VPL}$	Piecewise	Low voltage Ipcmd upper limit
S0	$S_0$	LagAntiWindupRate	
HVG	$H_{VG}$	GainLimiter	High voltage gain block
Iqout	$I^{qout}$	GainLimiter	Iq output block

## Config Fields in [REGCA1]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.20.2 REGCV1

### Group *RenGen*

Voltage-controlled VSC with VSG control.

Includes double-loop PI control and swing equation based VSG control. Voltage measurement delays are ignored.

### Parameters

Name	Sym- bol	Description	De- fault	Unit	Proper- ties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		interface bus id			mandatory
gen		static generator index			mandatory
coi2		center of inertia 2 index			
Sn	$S_n$	Model MVA base	100	<i>MVA</i>	
fn	$f$	rated frequency	60		
Tc	$T_c$	switch time constant	0.010	<i>s</i>	
kw	$k_\omega$	speed droop on active power (reciprocal of droop)	0	<i>p.u.</i>	ipower
kv	$k_v$	reactive power droop on voltage	0	<i>p.u.</i>	power
M	$M$	Emulated startup time constant (M=2H)	10	<i>s</i>	power
D	$D$	Emulated damping coefficient	0	<i>p.u.</i>	power
ra	$r_a$	resistance	0		<i>z</i>
xs	$x_s$	reactance	0.200		<i>z</i>
gammap	$\gamma_P$	P ratio of linked static gen	1		
gam- maq	$\gamma_Q$	Q ratio of linked static gen	1		
Kpvd	$kp_{vd}$	vd controller proportional gain	20	<i>p.u.</i>	power
Kivd	$ki_{vd}$	vd controller integral gain	0.001	<i>p.u.</i>	power
Kpvq	$kp_{vq}$	vq controller proportional gain	20	<i>p.u.</i>	power
Kivq	$ki_{vq}$	vq controller integral gain	0.001	<i>p.u.</i>	power
KpId	$kp_{di}$	Id controller proportional gain	500	<i>p.u.</i>	power

## 3.21 RenGovernor

Renewable turbine governor group.

Common Parameters:  $u$ , name, ree,  $w_0$ ,  $S_n$ ,  $Pe_0$

Common Variables:  $P_m$ ,  $w_{r0}$ ,  $w_t$ ,  $w_g$ ,  $s3\_y$

Available models: *WTDTA1*, *WTDS*

### 3.21.1 WTDTA1

Group *RenGovernor*

WTDTA wind turbine drive-train model.

One can set  $H_t\text{frac}$  to 0 to simulate a single-mass drive train.  $H_t\text{frac}$  has to be within  $[0, 1]$

User-provided reference speed should be specified in parameter  $w_0$ . Internally,  $w_0$  is set to the algebraic variable  $w_{r0}$ .

Note for PSS/E dyr parser:

In PSS/E doc, *Freq1* is said to be Hz, but exported data from PSS/E 34 uses per unit. ANDES requires *Freq1* in per unit frequency.

Parameters

Name	Sym- bol	Description	De- fault	Unit	Properties
idx		unique device idx			
$u$	$u$	connection status	1	<i>bool</i>	
name		device name			
ree		Renewable exciter idx			mandatory
$H$	$H_t$	Total inertia constant	3	<i>MWs/MVA</i>	non_zero,non_negative,power
DAMP	$D_{damp}$	Damp coefficient	0	<i>p.u. (gen base)</i>	power
$H_t\text{-frac}$	$D_{shaft}$	Turbine inertia fraction ( $H_{turb}/H$ )	0.500		power
<i>Freq1</i>	$F_{req1}$	First shaft torsional resonant frequency, p.u. (Hz)	1	<i>p.u. (Hz)</i>	
$D_{shaft}$	$D_{shaft}$	Shaft damping factor	1	<i>p.u. (gen base)</i>	power
$w_0$	$\omega_0$	Default speed if not using a torque model	1	<i>p.u.</i>	
reg			0		
$S_n$	$S_n$		0

adjust_upper		1	adjust upper limit	(0, 1)

### 3.21.2 WTDS

Group *RenGovernor*

Custom wind turbine model with a single swing-equation.

This model is used to simulate the mechanical swing of the combined machine and turbine mass.  
The speed output is `s1_y` which will be fed to `RenExciter.wg`.

PFLAG needs to be set to 1 in exciter to consider speed for Pref.

Parameters

Name	Sym- bol	Description	De- fault	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
ree		Renewable exciter idx			mandatory
H	$H_t$	Total inertia	3	<i>MWs/MVA</i>	non_zero,non_negative,power
D	$D_{shaft}$	Damping coefficient	1	<i>p.u.</i>	power
w0	$\omega_0$	Default speed if not using a torque model	1	<i>p.u.</i>	
reg			0		
Sn	$S_n$		0		

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
s1_y	$y_{s1}$	State	Integrator output		v_str
s3_y	$y_{s3}$	State	Unused state variable		
wt	$\omega_t$	AliasState	Alias of s1_y		
wg	$\omega_g$	AliasState	Alias of s1_y		
Pm	$P_m$	Algeb	Mechanical power		v_str
wr0	$\omega_{r0}$	Algeb	speed set point	<i>p.u.</i>	v_str

adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.23 RenPlant

Renewable plant control group.

Common Parameters: u, name

Available models: *REPCA1*

### 3.23.1 REPCA1

Group *RenPlant*

REPCA1 plat control model.

<PSS/E parser notice>

In PSS/E dyr file:

1. If ICONs M+1 and M+2 are set to 0 when using generator power, an error will be thrown by the parser, saying "<REPCA1> cannot retrieve <bus1> from <ACLine> using <line>: KeyError('Group <ACLine> does not contain device with idx=False')". Manual effort is required to run the converted file. In the REPCA1 sheet, input the idx of a line that connects to the RenGen bus.
2. PSS/E enters ICONs M+3 as a string in single quotes. The pair of single quotes need to be removed, or the conversion will fail.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
ree		RenExciter idx			mandatory
line		Idx of line that connect to measured bus			mandatory
busr		Optional remote bus for voltage and freq. measurement			
busf		BusFreq idx for mode 2			
VCFlag		Droop flag; 0-with droop if power factor ctrl, 1-line drop comp.		<i>bool</i>	mandatory
RefFlag		Q/V select; 0-Q control, 1-V control		<i>bool</i>	mandatory
Fflag		Frequency control flag; 0-disable, 1-enable		<i>bool</i>	mandatory
PLflag		Pline ctrl. flag; 0-disable, 1-enable	1	<i>bool</i>	
Tfltr	$T_{fltr}$	V or Q filter time const.	0.020		
Kp	$K_p$	Q proportional gain	1		
Ki	$K_i$	Q integral gain	0.100		
Tft	$T_{ft}$	Lead time constant	1		
Tfv	$T_{fv}$	Lag time constant	1		
Vfrz	$V_{frz}$	Voltage below which s2 is frozen	0.800		
Rc	$R_c$	Line drop compensation R			
Xc	$X_c$	Line drop compensation R			
Kc	$K_c$	Reactive power compensation gain	0		
emax	$e_{max}$	Upper limit on deadband output	999		
emin	$e_{min}$	Lower limit on deadband output	-999		
dbd1	$d_{bd1}$	Lower threshold for reactive power control deadband ( $\leq 0$ )	-0.100		
dbd2	$d_{bd2}$	Upper threshold for reactive power control deadband ( $\geq 0$ )	0.100		
Qmax	$Q_{max}$	Upper limit on output of V-Q control	999		
Qmin	$Q_{min}$	Lower limit on output of V-Q control	-999

freeze	$f_{rz}$	1	Voltage dip freeze flag; 1-enable, 0-disable	

## 3.24 RenTorque

Renewable torque (Pref) controller.

Common Parameters: u, name

Available models: *WTTQA1*

### 3.24.1 WTTQA1

Group *RenTorque*

Wind turbine generator torque (Pref) model.

PI state freeze following voltage dip has not been implemented.

Resets  $w_g$  in *REECA1* model to 1.0 when torque model is connected. This effectively ignores *PFLAG* of *REECA1*.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
rep		RenPitch controller idx			mandatory
Kip	$K_{ip}$	Pref-control integral gain	0.100	<i>p.u.</i>	
Kpp	$K_{pp}$	Pref-control proportional gain	0	<i>p.u.</i>	
TP	$T_p$	Pe sensing time const.	0.050	<i>s</i>	
Twref	$T_{wref}$	Speed reference time const.	30	<i>s</i>	
Temax	$T_{emax}$	Max. electric torque	1.200	<i>p.u.</i>	power
Temin	$T_{emin}$	Min. electric torque	0	<i>p.u.</i>	power
Tflag		Tflag; 1-power error, 0-speed error		<i>bool</i>	mandatory
p1	$p_1$	Active power point 1	0.200	<i>p.u.</i>	power
sp1	$s_{p1}$	Speed power point 1	0.580	<i>p.u.</i>

## 3.26 StaticGen

Static generator group for power flow calculation

Common Parameters: u, name, Sn, Vn, p0, q0, ra, xs, subidx

Common Variables: p, q, a, v

Available models: *PV*, *Slack*

### 3.26.1 PV

Group *StaticGen*

Static PV generator with reactive power limit checking and PV-to-PQ conversion.

$pv2pq = 1$  turns on the conversion. It starts from iteration  $min\_iter$  or when the convergence error drops below  $err\_tol$ .

The PV-to-PQ conversion first ranks the reactive violations. A maximum number of  $npv2pq$  PVs above the upper limit, and a maximum of  $npv2pq$  PVs below the lower limit will be converted to PQ, which sets the reactive power to  $pmax$  or  $pmin$ .

If  $pv2pq$  is 1 (enabled) and  $npv2pq$  is 0, heuristics will be used to determine the number of PVs to be converted for each iteration.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
Sn	$S_n$	Power rating	100		non_zero
Vn	$V_n$	AC voltage rating	110		non_zero
subidx		index for generators on the same bus			
bus		idx of the installed bus			mandatory
busr		bus idx for remote voltage control			
p0	$p_0$	active power set point in system base	0	<i>p.u.</i>	
q0	$q_0$	reactive power set point in system base	0	<i>p.u.</i>	
pmax	$p_{max}$	maximum active power in system base	999	<i>p.u.</i>	
pmin	$p_{min}$	minimum active power in system base	-1	<i>p.u.</i>	
qmax	$q_{max}$	maximum reactive power in system base	999	<i>p.u.</i>	
qmin	$q_{min}$	minimum reactive power in system base	-999	<i>p.u.</i>	
v0	$v_0$	voltage set point	1		
vmax	$v_{max}$	maximum voltage	1.400		
vmin	$v_{min}$	minimum allowed voltage	0.600		
ra	$r_a$	armature resistance	0		
xs	$x_s$	armature reactance	0.300		
busv0	$V_{0bus}$		0		

## Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties

## 3.27 StaticLoad

Static load group.

Common Parameters: u, name

Available models: *PQ*

### 3.27.1 PQ

#### Group *StaticLoad*

PQ load model.

Implements an automatic pq2z conversion during power flow when the voltage is outside [vmin, vmax]. The conversion can be turned off by setting *pq2z* to 0 in the Config file.

Before time-domain simulation, PQ load will be converted to impedance, current source, and power source based on the weights in the Config file.

Weights (p2p, p2i, p2z) corresponds to the weights for constant power, constant current and constant impedance. p2p, p2i and p2z must be in decimal numbers and sum up exactly to 1. The same rule applies to (q2q, q2i, q2z).

To alter the PQ load in terms of power during simulation, one needs to set the conversion weights to preserve the constant power portion. For example, the PQ can remain as constant power load by setting

```
ss.PQ.config.p2p = 1.0
ss.PQ.config.p2i = 0
ss.PQ.config.p2z = 0

ss.PQ.config.q2q = 1.0
ss.PQ.config.q2i = 0
ss.PQ.config.q2z = 0
```

Then, the constant power portion can be altered by changing the *Ppf* and *Qpf* constants for active power and reactive power.

The equivalent constant current components are in constants *Ipeq* and *Iqeq* for active and reactive current, and the equivalent impedances are in *Req* and *Xeq*.

#### Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		linked bus idx			mandatory
Vn	$V_n$	AC voltage rating	110	<i>kV</i>	non_zero
p0	$p_0$	active power load in system base	0	<i>p.u.</i>	
q0	$q_0$	reactive power load in system base	0	<i>p.u.</i>	
vmax	$v_{max}$	max voltage before switching to impedance	1.200		
vmin	$v_{min}$	min voltage before switching to impedance	0.800		
owner		owner idx			

#### Variables (States + Algebraics)

Option	Sym- bol	Value	Info	Accepted val- ues
al- low_adjust		1	allow adjusting upper or lower limits	(0, 1)
ad- just_lower		0	adjust lower limit	(0, 1)
ad- just_upper		1	adjust upper limit	(0, 1)
pq2z	$z_{pq2z}$	1	pq2z conversion if out of voltage limits	(0, 1)
p2p	$\gamma_{p2p}$	0	P constant power percentage for TDS. Must have (p2p+p2i+p2z)=1	float
p2i	$\gamma_{p2i}$	0	P constant current percentage	float
p2z	$\gamma_{p2z}$	1	P constant impedance percentage	float
q2q	$\gamma_{q2q}$	0	Q constant power percentage for TDS. Must have (q2q+q2i+q2z)=1	float
q2i	$\gamma_{q2i}$	0	Q constant current percentage	float
q2z	$\gamma_{q2z}$	1	Q constant impedance percentage	float

## 3.28 StaticShunt

Static shunt compensator group.

Common Parameters: u, name

Available models: *Shunt*, *ShuntTD*, *ShuntSw*

### 3.28.1 Shunt

Group *StaticShunt*

Phasor-domain shunt compensator Model.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		idx of connected bus			mandatory
Sn	$S_n$	Power rating	100		non_zero
Vn	$V_n$	AC voltage rating	110		non_zero
g	$g$	shunt conductance (real part)	0		y
b	$b$	shunt susceptance (positive as capacitive)	0		y
fn	$f_n$	rated frequency	60		

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
a	$\theta$	ExtAlgeb			
v	$V$	ExtAlgeb			

## Variable Initialization Equations

Name	Symbol	Type	Initial Value
a	$\theta$	ExtAlgeb	
v	$V$	ExtAlgeb	

## Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
a	$\theta$	ExtAlgeb	$V^2 g_u$
v	$V$	ExtAlgeb	$-V^2 b_u$

## Config Fields in [Shunt]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.28.2 ShuntTD

Group *StaticShunt*

Static shunt model with inverse transformation from phasor to time-domain.

## Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		idx of connected bus			mandatory
Sn	$S_n$	Power rating	100		non_zero
Vn	$V_n$	AC voltage rating	110		non_zero
g	$g$	shunt conductance (real part)	0		y
b	$b$	shunt susceptance (positive as capacitive)	0		y
fn	$f_n$	rated frequency	60		

## Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
vta	$V_{ta}$	Algeb			v_str
vtb	$V_{tb}$	Algeb			v_str
vtc	$V_{tc}$	Algeb			v_str
a	$\theta$	ExtAlgeb			
v	$V$	ExtAlgeb			

### Variable Initialization Equations

Name	Symbol	Type	Initial Value
vta	$V_{ta}$	Algeb	$\frac{\sqrt{3}V \cos(\theta + 2\pi f_{sys} t_{dae})}{3}$
vtb	$V_{tb}$	Algeb	$-\frac{\sqrt{3}V \cos(\theta + 2\pi f_{sys} t_{dae} + \frac{\pi}{3})}{3}$
vtc	$V_{tc}$	Algeb	$-\frac{\sqrt{3}V \sin(\theta + 2\pi f_{sys} t_{dae} + \frac{\pi}{6})}{3}$
a	$\theta$	ExtAlgeb	
v	$V$	ExtAlgeb	

### Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
vta	$V_{ta}$	Algeb	$\frac{\sqrt{3}V \cos(\theta + 2\pi f_{sys} t_{dae})}{3} - V_{ta}$
vtb	$V_{tb}$	Algeb	$-\frac{\sqrt{3}V \cos(\theta + 2\pi f_{sys} t_{dae} + \frac{\pi}{3})}{3} - V_{tb}$
vtc	$V_{tc}$	Algeb	$-\frac{\sqrt{3}V \sin(\theta + 2\pi f_{sys} t_{dae} + \frac{\pi}{6})}{3} - V_{tc}$
a	$\theta$	ExtAlgeb	$V^2 g_u$
v	$V$	ExtAlgeb	$-V^2 b_u$

### Config Fields in [ShuntTD]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.28.3 ShuntSw

### Group *StaticShunt*

Switched Shunt Model.

Parameters  $gs$ ,  $bs$  and  $bs$  must be entered in string literals, comma-separated. They need to have the same length.

For example, in the excel file, one can put

```
gs = [0, 0]
bs = [0.2, 0.2]
ns = [2, 4]
```

To use individual shunts as fixed shunts, set the corresponding  $ns = 0$  or  $ns = [0]$ .

The effective shunt susceptances and conductances are stored in services *beff* and *geff*.

#### Parameters

Name	Sym- bol	Description	De- fault	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		idx of connected bus			mandatory
Sn	$S_n$	Power rating	100		non_zero
Vn	$V_n$	AC voltage rating	110		non_zero
g	$g$	shunt conductance (real part)	0		y
b	$b$	shunt susceptance (positive as capacitive)	0		y
fn	$f_n$	rated frequency	60		
gs		a list literal of switched conductances blocks	0	<i>p.u.</i>	y
bs		a list literal of switched susceptances blocks	0	<i>p.u.</i>	y
ns		a list literal of the element numbers in each switched block	[0]		
vref		voltage reference	1	<i>p.u.</i>	non_zero,non_negative
dv		voltage error deadband	0.050	<i>p.u.</i>	non_zero,non_negative
dt		delay before two consecutive switching	30	<i>sec- onds</i>	non_negative

#### Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
a	$\theta$	ExtAlgeb			
v	$V$	ExtAlgeb			

#### Variable Initialization Equations

Name	Symbol	Type	Initial Value
a	$\theta$	ExtAlgeb	
v	$V$	ExtAlgeb	

#### Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
a	$\theta$	ExtAlgeb	$V^2_{geffu}$
v	$V$	ExtAlgeb	$-V^2_{befu}$

### Services

Name	Symbol	Equation	Type
vlo	$v_{lo}$	$-dv + vref$	ConstService
vup	$v_{up}$	$dv + vref$	ConstService

### Discrete

Name	Symbol	Type	Info
adj	$adj$	ShuntAdjust	shunt adjuster

### Config Fields in [ShuntSw]

Option	Sym- bol	Value	Info	Accepted val- ues
al- low_adjust		1	allow adjusting upper or lower limits	(0, 1)
ad- just_lower		0	adjust lower limit	(0, 1)
ad- just_upper		1	adjust upper limit	(0, 1)
min_iter	$sw_{iter}$	2	iteration number starting from which to enable switching	int
err_tol	$\epsilon_{tol}$	0.010	iteration error below which to enable switching	float

## 3.29 SynGen

Synchronous generator group.

Common Parameters: u, name, Sn, Vn, fn, bus, M, D, subidx

Common Variables: omega, delta, tm, te, vf, XadIfd, vd, vq, Id, Iq, a, v

Available models: *GENCLS*, *GENROU*, *PLBVFUI*

### 3.29.1 GENCLS

Group *SynGen*

Classical generator model.

Parameters

Name	Sym- bol	Description	De- fault	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		interface bus id			mandatory
gen		static generator index			mandatory
coi		center of inertia index			
coi2		center of inertia index			
Sn	$S_n$	Power rating	100	<i>MVA</i>	
Vn	$V_n$	AC voltage rating	110		
fn	$f$	rated frequency	60		
D	$D$	Damping coefficient	0		power
M	$M$	machine start up time (2H)	6		non_zero,non_negative,power
ra	$r_a$	armature resistance	0		z
xl	$x_l$	leakage reactance	0		z
xd1	$x'_d$	d-axis transient reactance	0.302		z
kp	$k_p$	active power feedback gain	0		
kw	$k_w$	speed feedback gain	0		
S10	$S_{1.0}$	first saturation factor	0		
S12	$S_{1.2}$	second saturation factor	1		
gammap	$\gamma_P$	P ratio of linked static gen	1		
gam- maq	$\gamma_Q$	Q ratio of linked static gen	1		
subidx		Generator idx in plant; only used by PSS/E data	0		

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
delta	$\delta$	State	rotor angle	<i>rad</i>	v_str
omega	$\omega$	State	rotor speed	<i>pu (Hz)</i>	v_str
Id	$I_d$	Algeb	d-axis current		v_str
Iq	$I_q$	Algeb	q-axis current		v_str
vd	$V_d$	Algeb	d-axis voltage		v_str
vq	$V_q$	Algeb	q-axis voltage		v_str
tm	$\tau_m$	Algeb	mechanical torque		v_str
te	$\tau_e$	Algeb	electric torque		v_str
vf	$v_f$	Algeb	excitation voltage	<i>pu</i>	v_str
XadIfd	$X_{ad}I_{fd}$	Algeb	d-axis armature excitation current	<i>p.u (kV)</i>	v_str
Pe	$P_e$	Algeb	active power injection		v_str
Qe	$Q_e$	Algeb	reactive power injection		v_str
psid	$\psi_d$	Algeb	d-axis flux		v_str
psiq	$\psi_q$	Algeb	q-axis flux		v_str
a	$\theta$	ExtAlgeb	Bus voltage phase angle		
v	$V$	ExtAlgeb	Bus voltage magnitude		

### Variable Initialization Equations

Name	Symbol	Type	Initial Value
delta	$\delta$	State	$\delta_0$
omega	$\omega$	State	$u$
Id	$I_d$	Algeb	$I_{d0}u$
Iq	$I_q$	Algeb	$I_{q0}u$
vd	$V_d$	Algeb	$V_{d0}u$
vq	$V_q$	Algeb	$V_{q0}u$
tm	$\tau_m$	Algeb	$\tau_{m0}$
te	$\tau_e$	Algeb	$\tau_{m0}u$
vf	$v_f$	Algeb	$uvf_0$
XadIfd	$X_{ad}I_{fd}$	Algeb	$uvf_0$
Pe	$P_e$	Algeb	$u(I_{d0}V_{d0} + I_{q0}V_{q0})$
Qe	$Q_e$	Algeb	$u(I_{d0}V_{q0} - I_{q0}V_{d0})$
psid	$\psi_d$	Algeb	$\psi_{d0}u$
psiq	$\psi_q$	Algeb	$\psi_{q0}u$
a	$\theta$	ExtAlgeb	
v	$V$	ExtAlgeb	

### Differential Equations

Name	Symbol	Type	RHS of Equation "T x' = f(x, y)"	T (LHS)
delta	$\delta$	State	$2\pi f u (\omega - 1)$	
omega	$\omega$	State	$u(-D(\omega - 1) - \tau_e + \tau_m)$	$M$

### Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
Id	$I_d$	Algeb	$I_d x q + \psi_d - v_f$
Iq	$I_q$	Algeb	$I_q x q + \psi_q$
vd	$V_d$	Algeb	$V u \sin(\delta - \theta) - V_d$
vq	$V_q$	Algeb	$V u \cos(\delta - \theta) - V_q$
tm	$\tau_m$	Algeb	$-\tau_m + \tau_{m0}$
te	$\tau_e$	Algeb	$-\tau_e + u(-I_d \psi_q + I_q \psi_d)$
vf	$v_f$	Algeb	$u v_{f0} - v_f$
XadIfd	$X_{ad} I_{fd}$	Algeb	$-X_{ad} I_{fd} + u v_{f0}$
Pe	$P_e$	Algeb	$-P_e + u(I_d V_d + I_q V_q)$
Qe	$Q_e$	Algeb	$-Q_e + u(I_d V_q - I_q V_d)$
psid	$\psi_d$	Algeb	$-\psi_d + u(I_q r_a + V_q)$
psiq	$\psi_q$	Algeb	$\psi_q + u(I_d r_a + V_d)$
a	$\theta$	ExtAlgeb	$-u(I_d V_d + I_q V_q)$
v	$V$	ExtAlgeb	$-u(I_d V_q - I_q V_d)$

## Services

Name	Symbol	Equation	Type
p0	$P_0$	$P_{0s} \gamma_P$	ConstService
q0	$Q_0$	$Q_{0s} \gamma_Q$	ConstService
_V	$V_c$	$V e^{i\theta}$	ConstService
_S	$S$	$P_0 - i Q_0$	ConstService
_I	$I_c$	$\frac{S}{\text{conj}(V_c)}$	ConstService
_E	$E$	$I_c(r_a + i x q) + V_c$	ConstService
_deltac	$\delta_c$	$\log\left(\frac{E}{ E }\right)$	ConstService
delta0	$\delta_0$	$u \text{im}(\delta_c)$	ConstService
vdq	$V_{dq}$	$V_c u e^{-\delta_c + 0.5i\pi}$	ConstService
Idq	$I_{dq}$	$I_c u e^{-\delta_c + 0.5i\pi}$	ConstService
Id0	$I_{d0}$	$\text{re}(I_{dq})$	ConstService
Iq0	$I_{q0}$	$\text{im}(I_{dq})$	ConstService
vd0	$V_{d0}$	$\text{re}(V_{dq})$	ConstService
vq0	$V_{q0}$	$\text{im}(V_{dq})$	ConstService
tm0	$\tau_{m0}$	$u(I_{d0}(I_{d0} r_a + V_{d0}) + I_{q0}(I_{q0} r_a + V_{q0}))$	ConstService
psid0	$\psi_{d0}$	$I_{q0} r_a u + V_{q0}$	ConstService
psiq0	$\psi_{q0}$	$-I_{d0} r_a u - V_{d0}$	ConstService
vf0	$v_{f0}$	$I_{d0} x q + I_{q0} r_a + V_{q0}$	ConstService

## Config Fields in [GENCLS]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)
vf_lower		1	lower limit for vf warning	
vf_upper		5	upper limit for vf warning	

### 3.29.2 GENROU

Group *SynGen*

Round rotor generator with quadratic saturation.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		interface bus id			mandatory
gen		static generator index			mandatory
coi		center of inertia index			
coi2		center of inertia index			
Sn	$S_n$	Power rating	100	MVA	
Vn	$V_n$	AC voltage rating	110		
fn	$f$	rated frequency	60		
D	$D$	Damping coefficient	0		power
M	$M$	machine start up time (2H)	6		non_zero,non_negative,power
ra	$r_a$	armature resistance	0		z
xl	$x_l$	leakage reactance	0		z
xd1	$x'_d$	d-axis transient reactance	0.302		z
kp	$k_p$	active power feedback gain	0		
kw	$k_w$	speed feedback gain	0		
S10	$S_{1.0}$	first saturation factor	0		
S12	$S_{1.2}$	second saturation factor	1		
gammap	$\gamma_P$	P ratio of linked static gen	1		
gammaq	$\gamma_Q$	Q ratio of linked static gen	1		
xd	$x_d$	d-axis synchronous reactance	1.900		z
xq	$x_q$	q-axis synchronous reactance	1.700		z
xd2	$x''_d$	d-axis sub-transient reactance	0.204		z
xq1	$x'_q$	q-axis transient reactance	0.500		z
xq2	$x''_q$	q-axis sub-transient reactance	0.300		z
Td10	$T'_{d0}$	d-axis transient time constant	8		
Td20	$T''_{d0}$	d-axis sub-transient time constant	0.040		
Tq10	$T'_{q0}$	q-axis transient time constant	0.800		

continues on next page

Table 34 – continued from previous page

Name	Symbol	Description	Default	Unit	Properties
Tq20	$T''_{q0}$	q-axis sub-transient time constant	0.020		
subidx		Generator idx in plant; only used by PSS/E data	0		

## Variables (States + Algebraics)

### 3.29.3 PLBVFU1

Group *SynGen*

PLBVFU1 model: playback of voltage and frequency as a generator.

The internal voltage and frequency are named `Vflt` and `omega`. Rotor angle is named `delta`.

The current implementation relies on a `TimeSeries` device to provide the voltage and frequency signals. See `ieee14_plbvf1.xlsx` and `plbvf.xlsx` in `andes/cases/ieee14` for an example.

Voltage and frequency data needs to be specified in per unit. Nominal values are not yet supported.

Parameters

Name	Sym- bol	Description	De- fault	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		interface bus id			mandatory
gen		static generator index			mandatory
Sn	$S_n$	Power rating	100	<i>MVA</i>	
Vn	$V_n$	AC voltage rating	110		
ra	$r_a$	armature resistance	0		z
xs	$x_s$	generator transient reactance	0.200		non_zero,z
fn	$f_n$	rated frequency	60		
Vflag		playback voltage signal	1	<i>bool</i>	
fflag		playback frequency signal	1	<i>bool</i>	
file- name		playback file name		<i>string</i>	mandatory
Vscale	$V_{scale}$	playback voltage scale	1	<i>pu</i>	non_negative
fscale	$f_{scale}$	playback frequency scale	1	<i>pu</i>	non_negative
Tv	$T_v$	filtering time constant for voltage	0.200	<i>s</i>	non_negative
Tf	$T_f$	filtering time constant for frequency	0.200	<i>s</i>	non_negative
subidx		Generator idx in plant; only used by PSS/E data	0		

## Variables (States + Algebras)

Name	Symbol	Type	Description	Unit	Properties
Vflt	$V_{flt}$	State	filtered voltage	<i>pu</i>	v_str
omega	$\omega$	State	filtered frequency	<i>pu</i>	v_str
delta	$\delta$	State	rotor angle	<i>rad</i>	v_str
a	$\theta$	ExtAlgeb	Bus voltage phase angle		
v	$V$	ExtAlgeb	Bus voltage magnitude		

## Variable Initialization Equations

Name	Symbol	Type	Initial Value
Vflt	$V_{flt}$	State	$1/V_{scale}V_{ts} - V_{offs}$
omega	$\omega$	State	$1/f_{scale}f_{ts} - f_{offs}$
delta	$\delta$	State	$\delta_0$
a	$\theta$	ExtAlgeb	
v	$V$	ExtAlgeb	

## Differential Equations

Name	Symbol	Type	RHS of Equation "T x' = f(x, y)"	T (LHS)
Vflt	$V_{flt}$	State	$1/V_{scale}V_{ts} - V_{flt} - V_{offs}$	$T_v$
omega	$\omega$	State	$1/f_{scale}fts - \omega - f_{offs}$	$T_f$
delta	$\delta$	State	$2\pi f_n u (\omega - 1)$	

## Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
a	$\theta$	ExtAlgeb	$-\frac{VV_{flt}x_s \sin(\delta-\theta)}{r_a^2+x_s^2} + \frac{Vr_a(V-V_{flt} \cos(\delta-\theta))}{r_a^2+x_s^2}$
v	$V$	ExtAlgeb	$\frac{VV_{flt}r_a \sin(\delta-\theta)}{r_a^2+x_s^2} + \frac{Vx_s(V-V_{flt} \cos(\delta-\theta))}{r_a^2+x_s^2}$

## Services

Name	Symbol	Equation	Type
zs	$zs$	$r_a + ix_s$	ConstService
zs2n	$zs2n$	$r_a^2 - x_s^2$	ConstService

foffs	$f_{offs}$	$1/f_{scale}fts - 1$	ConstService
Voffs	$V_{offs}$	$1/V_{scale}V_{ts} - E_0$	ConstService

## Config Fields in [PLBVFU1]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

### 3.30 TimedEvent

Timed event group

Common Parameters: u, name

Available models: *Toggler*, *Fault*, *Alter*

### 3.30.1 Toggler

Group *TimedEvent*

Time-based connectivity status toggler.

Toggler is used to toggle the connection status of a device at a predefined time. Both the model name (or group name) and the device idx need to be provided.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	<i>u</i>	connection status	1	<i>bool</i>	
name		device name			
model		model or group name of the device			mandatory
dev		idx of the device to control			mandatory
t		switch time for connection status	-1		mandatory

Services

Name	Symbol	Equation	Type
<i>_u</i>	<i>u</i>	1	ConstService

Config Fields in [Toggler]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

### 3.30.2 Fault

Group *TimedEvent*

Three-phase to ground fault.

Two times, *tf* and *tc*, can be defined for fault on for fault clearance.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		linked bus idx			mandatory
tf		Bus fault start time	-1	<i>second</i>	mandatory
tc		Bus fault end time	-1	<i>second</i>	
xf	$x_f$	Fault to ground impedance (positive)	0.000	<i>p.u.(sys)</i>	
rf	$x_f$	Fault to ground resistance (positive)	0	<i>p.u.(sys)</i>	

## Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
a	$\theta$	ExtAlgeb	Bus voltage angle	<i>p.u.(kV)</i>	
v	$V$	ExtAlgeb	Bus voltage magnitude	<i>p.u.(kV)</i>	

## Variable Initialization Equations

Name	Symbol	Type	Initial Value
a	$\theta$	ExtAlgeb	
v	$V$	ExtAlgeb	

## Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
a	$\theta$	ExtAlgeb	$V^2 g_f u u_f$
v	$V$	ExtAlgeb	$-V^2 b_f u u_f$

## Services

Name	Symbol	Equation	Type
gf	$g_f$	$\frac{\operatorname{re}(x_f) - \operatorname{im}(x_f)}{(\operatorname{re}(x_f) - \operatorname{im}(x_f))^2 + (\operatorname{re}(x_f) + \operatorname{im}(x_f))^2}$	ConstService
bf	$b_f$	$\frac{-\operatorname{re}(x_f) - \operatorname{im}(x_f)}{(\operatorname{re}(x_f) - \operatorname{im}(x_f))^2 + (\operatorname{re}(x_f) + \operatorname{im}(x_f))^2}$	ConstService
uf	$u_f$	0	ConstService

## Config Fields in [Fault]

Option	Sym- bol	Value	Info	Accepted val- ues
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
ad- just_lower		0	adjust lower limit	(0, 1)
ad- just_upper		1	adjust upper limit	(0, 1)
restore		1	restore algebraic variables to pre-fault values	(0, 1)
mode		1	1 - restore voltages on all buses, 2 - fault bus only	(1, 2)
scale		1	scaling factor of restored algebraic values	

### 3.30.3 Alter

Group *TimedEvent*

Model for altering device internal data (service or param) at a given time.

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	<i>u</i>	connection status	1	<i>bool</i>	
name		device name			
t		switch time for connection status	-1		mandatory
model		model or group name of the device			mandatory
dev		idx of the device to alter			mandatory
src		model source field (param or service)			mandatory
attr		attribute (e.g., v) of the source field	v		
method		alteration method in +, -, *, /, =			mandatory
amount		the amount to apply			mandatory
rand		use uniform random sampling	0		
lb		lower bound of random sampling	0		
ub		upper bound of random sampling	0		

Discrete

Name	Symbol	Type	Info
SW	<i>SW</i>	Switcher	Switcher for alteration method

Config Fields in [Alter]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

### 3.31 TurbineGov

Turbine governor group for synchronous generator.

Common Parameters: u, name

Common Variables: pout

Available models: *TG2*, *TGOV1*, *TGOVIDB*, *TGOVIN*, *TGOVINDB*, *IEEEG1*, *IEESGO*, *GAST*, *HYGOV*, *HYGOVDB*

#### 3.31.1 TG2

Group *TurbineGov*

Parameters

Name	Sym- bol	Description	De- fault	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
syn		Synchronous generator idx			manda- tory,unique
Tn	$T_n$	Turbine power rating. Equal to $S_n$ if not provided.		<i>MVA</i>	
wref0	$\omega_{ref0}$	Base speed reference	1	<i>p.u.</i>	
R	$R$	Speed regulation gain (mach. base default)	0.050	<i>p.u.</i>	ipower
pmax	$p_{max}$	Maximum power output	999	<i>p.u.</i>	power
pmin	$p_{min}$	Minimum power output	0	<i>p.u.</i>	power
dbl	$L_{db}$	Deadband lower limit	-0.000	<i>p.u.</i>	
dbu	$U_{db}$	Deadband upper limit	0.000	<i>p.u.</i>	
dbc	$C_{db}$	Deadband neutral value	0	<i>p.u.</i>	
T1	$T_1$	Transient gain time	0.200		
T2	$T_2$	Governor time constant	10		
Sg	$S_n$	Rated power from generator	0	<i>MVA</i>	
ug	$u_g$	Generator connection status	0	<i>bool</i>	
Vn	$V_n$	Rated voltage from generator	0	<i>kV</i>	

Variables (States + Algebraics)

Name	Sym- bol	Type	Description	Unit	Proper- ties
ll_x	$x'_{ll}$	State	State in lead-lag		v_str
omega	$\omega$	ExtState	Generator speed	<i>p.u.</i>	
paux	$P_{aux}$	Algeb	Auxiliary power input		v_str
pout	$P_{out}$	Algeb	Turbine final output power		v_str
wref	$\omega_{ref}$	Algeb	Speed reference variable		v_str
w_d	$\omega_{dev}$	Algeb	Generator speed deviation before dead band (positive for under speed)		v_str
w_dm	$\omega_{dm}$	Algeb	Measured speed deviation after dead band		v_str
w_dmG	$\omega_{dmG}$	Algeb	Speed deviation after dead band after gain		v_str
ll_y	$y_{ll}$	Algeb	Output of lead-lag		v_str
pnl	$P_{nl}$	Algeb	Power output before hard limiter		v_str
tm	$\tau_m$	ExtAl- geb	Mechanical power interface to SynGen		

### Variable Initialization Equations

Name	Symbol	Type	Initial Value
ll_x	$x'_{ll}$	State	$\omega_{dmG}$

### 3.31.4 TGOV1N

Group *TurbineGov*

New TGOV1 (TGOV1N) turbine governor model.

New TGOV1 model with *pref* and *paux* summed after the gain. This model is useful for incorporating AGC and scheduling signals without having to know the droop.

Scheduling changes should write to the *v* fields of *pref0* and *qref0* in place. AGC signal should write to that of *paux0* in place.

Modifying *tm0* is not allowed.

Parameters

Name	Sym- bol	Description	De- fault	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name

adjust_upper		1	adjust upper limit	(0, 1)

### 3.31.6 IEEEG1

Group *TurbineGov*

IEEE Type 1 Speed-Governing Model.

If only one generator is connected, its *idx* must be given to *syn*, and *syn2* must be left blank. Each generator must provide data in its *Sn* base.

*syn* is connected to the high-pressure output (PHP) and the optional *syn2* is connected to the low- pressure output (PLP).

The speed deviation of generator 1 (*syn*) is measured. If the turbine rating *Tn* is not specified, the sum of *Sn* of all connected generators will be used.

Normally,  $K1 + K2 + \dots + K8 = 1.0$ . If the second generator is not connected,  $K1 + K3 + K5 + K7 = 1$ , and  $K2 + K4 + K6 + K8 = 0$ .

IEEEG1 does not yet support the change of reference (scheduling).

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>

## 3.32 Undefined

The undefined group. Holds models with no group.

Common Parameters: u, name

Available models: *TimeSeries*, *PLL1*

### 3.32.1 TimeSeries

Group *Undefined*

Model for metadata of timeseries.

TimeSeries will not overwrite values in power flow.

Relative path is assumed in the same folder as the case file.

Parameters

Name	Sym- bol	Description	De- fault	Unit	Proper- ties
idx		unique device idx			
u	<i>u</i>	connection status	1	<i>bool</i>	
name		device name			
mode		Mode for applying timeseries. 1: exact time, 2: inter- polated	1		
path		Path to timeseries.xlsx file.			manda- tory
sheet		Sheet name to use			manda- tory

### 3.32.2 PLL1

Group *Undefined*

Simple Phasor Lock Loop (PLL) using one PI controller.

**Input bus angle signal** -> Lag filter 1 with  $T_f$  -> PI Controller ( $K_p$ ,  $K_i$ ) -> Estimated angle ( $2 \pi \cdot f_n \cdot PI\_y$ ) -> Lag filter 2 with  $T_p$

The output signal is  $am$ .

Parameters

Name	Symbol	Description	Default	Unit	Properties
idx		unique device idx			
u	$u$	connection status	1	<i>bool</i>	
name		device name			
bus		bus idx			mandatory
$K_p$	$K_p$	proportional gain	1		
$K_i$	$K_i$	integral gain	0.200		
$T_f$	$T_f$	input digital filter time const	0.050	<i>sec</i>	
$T_p$	$T_p$	output filter time const.	0.050	<i>sec</i>	
$f_n$	$f_n$	nominal frequency	60	<i>Hz</i>	

Variables (States + Algebraics)

Name	Symbol	Type	Description	Unit	Properties
af_y	$y_{af}$	State	State in lag transfer function		v_str
PI_xi	$xi_{PI}$	State	Integrator output		v_str
ae	$\theta_{est}$	State	PLL angle output before filter		v_str
am	$\theta_{PLL}$	State	PLL output angle after filtering		v_str
PI_y	$y_{PI}$	Algeb	PI output		v_str
a	$\theta$	ExtAlgeb	Bus voltage angle		

Variable Initialization Equations

Name	Symbol	Type	Initial Value
af_y	$y_{af}$	State	$\theta$
PI_xi	$x_{iPI}$	State	0.0
ae	$\theta_{est}$	State	$\theta$

PI_y	$y_{PI}$	Algeb	$K_p u (-\theta_{PLL} + y_{af})$
a	$\theta$	ExtAlgeb	

### Differential Equations

Name	Symbol	Type	RHS of Equation "T x' = f(x, y)"	T (LHS)
af_y	$y_{af}$	State	$\theta - y_{af}$	$T_f$
PI_xi	$x_{iPI}$	State	$K_i u (-\theta_{PLL} + y_{af})$	
ae	$\theta_{est}$	State	$2\pi f_n y_{PI}$	
am	$\theta_{PLL}$	State	$-\theta_{PLL} + \theta_{est}$	$T_p$

### Algebraic Equations

Name	Symbol	Type	RHS of Equation "0 = g(x, y)"
PI_y	$y_{PI}$	Algeb	$K_p u (-\theta_{PLL} + y_{af}) + x_{iPI} - y_{PI}$
a	$\theta$	ExtAlgeb	0

### Blocks

Name	Symbol	Type	Info
af	$af$	Lag	input angle signal filter
PI	$PI$	PIController	PI controller

### Config Fields in [PLL1]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## 3.33 VoltComp

Voltage compensator group for synchronous generators.

Common Parameters: u, name, rc, xc

Common Variables: vcomp

Available models: *IEEEVC*

### 3.33.1 IEEEVC

#### Group *VoltComp*

Voltage compensator IEEEVC model.

Reference:

[1] PowerWorld, Voltage Compensator, IEEEVC, [Online],

Eterm	$Eterm$	ExtAlgeb	$v_{comp}$

## Services

Name	Symbol	Equation	Type
vct	$V_{CT}$	$u  V_d + iV_q + (I_d + iI_q)(r_c + ix_c) $	VarService

## Config Fields in [IEEEVC]

Option	Symbol	Value	Info	Accepted values
allow_adjust		1	allow adjusting upper or lower limits	(0, 1)
adjust_lower		0	adjust lower limit	(0, 1)
adjust_upper		1	adjust upper limit	(0, 1)

## DEVELOPMENT

This chapter contains advanced topics on modeling and simulation and how they are implemented in ANDES. It aims to provide an in-depth explanation of how the ANDES framework is set up for symbolic modeling and numerical simulation. It also provides an example for interested users to implement customized DAE models.

## 4.1 System

### 4.1.1 Overview

System is the top-level class for organizing power system models and orchestrating calculations. The full API reference of System is found at [andes.system.System](#).

#### Dynamic Imports

System dynamically imports groups, models, and routines at creation. To add new models, groups or routines, edit the corresponding file by adding entries following examples.

```
andes.system.System.import_models(self)
```

Import and instantiate models as System member attributes.

Models defined in `models/__init__.py` will be instantiated *sequentially* as attributes with the same name as the class name. In addition, all models will be stored in dictionary `System.models` with model names as keys and the corresponding instances as values.

#### Examples

`system.Bus` stores the *Bus* object, and `system.GENCLS` stores the classical generator object,

`system.models['Bus']` points the same instance as `system.Bus`.

```
andes.system.System.import_groups(self)
```

Import all groups classes defined in `devices/group.py`.

Groups will be stored as instances with the name as class names. All groups will be stored to dictionary `System.groups`.

`andes.system.System.import_routines(self)`

Import routines as defined in `routines/__init__.py`.

Routines will be stored as instances with the name as class names. All groups will be stored to dictionary `System.groups`.

## Examples

`System.PFlow` is the power flow routine instance, and `System.TDS` and `System.EIG` are time-domain analysis and eigenvalue analysis routines, respectively.

## Code Generation

Under the hood, all symbolically defined equations need to be generated into anonymous function calls for accelerating numerical simulations. This process is automatically invoked for the first time ANDES is run command line. It takes several seconds up to a minute to finish the generation.

---

**Note:** Code generation has been done if one has executed `andes`, `andes selftest`, or `andes prepare`.

---

**Warning:** When models are modified (such as adding new models or changing equation strings), code generation needs to be executed again for consistency. It can be more conveniently triggered from command line with `andes prepare -i`.

`andes.system.System.prepare(self, quick=False, incremental=False, models=None, nomp=False, ncpu=1)`

Generate numerical functions from symbolically defined models.

All procedures in this function must be independent of test case.

### Parameters

**quick** [bool, optional] True to skip pretty-print generation to reduce code generation time.

**incremental** [bool, optional] True to generate only for modified models, incrementally.

**models** [list, OrderedDict, None] List or OrderedDict of models to prepare

**nomp** [bool] True to disable multiprocessing

**Warning:** Generated lambda functions will be serialized to file, but pretty prints (SymPy objects) can only exist in the System instance on which prepare is called.

## Notes

Option `incremental` compares the md5 checksum of all var and service strings, and only regenerate for updated models.

## Examples

If one needs to print out LaTeX-formatted equations in a Jupyter Notebook, one need to generate such equations with

```
import andes
sys = andes.prepare()
```

Alternatively, one can explicitly create a System and generate the code

```
import andes
sys = andes.System()
sys.prepare()
```

Since the process is slow, generated numerical functions (Python Callable) will be serialized into a file for future speed up. The package used for serializing/de-serializing numerical calls is `dill`. System has a function called `dill` for serializing using the `dill` package.

`andes.system.System.dill(self)`

Serialize generated numerical functions in `System.calls` with package `dill`.

The serialized file will be stored to `~/ .andes/calls.pkl`, where `~` is the home directory path.

## Notes

This function sets `dill.settings['recurse'] = True` to serialize the function calls recursively.

`andes.system.System.undill(self)`

Deserialize the function calls from `~/ .andes/calls.pkl` with `dill`.

If no change is made to models, future calls to `prepare()` can be replaced with `undill()` for acceleration.

### 4.1.2 DAE Storage

`System.dae` is an instance of the numerical DAE class.

`andes.variables.dae.DAE(system)`

Class for storing numerical values of the DAE system, including variables, equations and first order derivatives (Jacobian matrices).

Variable values and equation values are stored as `numpy.ndarray`, while Jacobians are stored as `kvxopt.spmatrix`. The defined arrays and descriptions are as follows:

DAE Array	Description
x	Array for state variable values
y	Array for algebraic variable values
z	Array for 0/1 limiter states (if enabled)
f	Array for differential equation derivatives
Tf	Left-hand side time constant array for f
g	Array for algebraic equation mismatches

The defined scalar member attributes to store array sizes are

Scalar	Description
m	The number of algebraic variables/equations
n	The number of algebraic variables/equations
o	The number of limiter state flags

The derivatives of  $f$  and  $g$  with respect to  $x$  and  $y$  are stored in four `kvxopt.spmatrix` sparse matrices: **fx**, **fy**, **gx**, and **gy**, where the first letter is the equation name, and the second letter is the variable name.

## Notes

DAE in ANDES is defined in the form of

$$\begin{aligned}T\dot{x} &= f(x, y) \\ 0 &= g(x, y)\end{aligned}$$

DAE does not keep track of the association of variable and address. Only a variable instance keeps track of its addresses.

### 4.1.3 Model and DAE Values

ANDES uses a decentralized architecture between models and DAE value arrays. In this architecture, variables are initialized and equations are evaluated inside each model. Then, `System` provides methods for collecting initial values and equation values into DAE, as well as copying solved values to each model.

The collection of values from models needs to follow protocols to avoid conflicts. Details are given in the subsection `Variables`.

```
andes.system.System.vars_to_dae(self, model)
```

Copy variables values from models to `System.dae`.

This function clears `DAE.x` and `DAE.y` and collects values from models.

```
andes.system.System.vars_to_models(self)
```

Copy variable values from `System.dae` to models.

```
andes.system.System._e_to_dae(self, eq_name: Union[str, Tuple] = ('f', 'g'))
```

Helper function for collecting equation values into `System.dae.f` and `System.dae.g`.

## Parameters

**eq\_name** ['x' or 'y' or tuple] Equation type name

## Matrix Sparsity Patterns

The largest overhead in building and solving nonlinear equations is the building of Jacobian matrices. This is especially relevant when we use the implicit integration approach which algebraized the differential equations. Given the unique data structure of power system models, the sparse matrices for Jacobians are built **incrementally**, model after model.

There are two common approaches to incrementally build a sparse matrix. The first one is to use simple in-place add on sparse matrices, such as doing

```
self.fx += spmatrix(v, i, j, (n, n), 'd')
```

Although the implementation is simple, it involves creating and discarding temporary objects on the right hand side and, even worse, changing the sparse pattern of `self.fx`.

The second approach is to store the rows, columns and values in an array-like object and construct the Jacobians at the end. This approach is very efficient but has one caveat: it does not allow accessing the sparse matrix while building.

ANDES uses a pre-allocation approach to avoid the change of sparse patterns by filling values into a known the sparse matrix pattern matrix. System collects the indices of rows and columns for each Jacobian matrix. Before in-place additions, ANDES builds a temporary zero-filled *spmatrix*, to which the actual Jacobian values are written later. Since these in-place add operations are only modifying existing values, it does not change the pattern and thus avoids memory copying. In addition, updating sparse matrices can be done with the exact same code as the first approach.

Still, this approach creates and discards temporary objects. It is however feasible to write a C function which takes three array-likes and modify the sparse matrices in place. This is feature to be developed, and our prototype shows a promising acceleration up to 50%.

`andes.system.System.store_sparse_pattern(self, models: collections.OrderedDict)`

Collect and store the sparsity pattern of Jacobian matrices.

This is a runtime function specific to cases.

## Notes

For gy matrix, always make sure the diagonal is reserved. It is a safeguard if the modeling user omitted the diagonal term in the equations.

### 4.1.4 Calling Model Methods

System is an orchestrator for calling shared methods of models. These API methods are defined for initialization, equation update, Jacobian update, and discrete flags update.

The following methods take an argument *models*, which should be an *OrderedDict* of models with names as keys and instances as values.

**andes.system.System.init**(*self*, *models*: *collections.OrderedDict*, *routine*: *str*)

Initialize the variables for each of the specified models.

For each model, the initialization procedure is:

- Get values for all *ExtService*.
- Call the model *init()* method, which initializes internal variables.
- Copy variables to DAE and then back to the model.

**andes.system.System.e\_clear**(*self*, *models*: *collections.OrderedDict*)

Clear equation arrays in DAE and model variables.

This step must be called before calling *f\_update* or *g\_update* to flush existing values.

**andes.system.System.l\_update\_var**(*self*, *models*: *collections.OrderedDict*, *niter*=None, *err*=None)

Update variable-based limiter discrete states by calling *l\_update\_var* of models.

This function is must be called before any equation evaluation.

**andes.system.System.f\_update**(*self*, *models*: *collections.OrderedDict*)

Call the differential equation update method for models in sequence.

#### Notes

Updated equation values remain in models and have not been collected into DAE at the end of this step.

**andes.system.System.l\_update\_eq**(*self*, *models*: *collections.OrderedDict*, *init*=False)

Update equation-dependent limiter discrete components by calling *l\_check\_eq* of models. Force set equations after evaluating equations.

This function is must be called after differential equation updates.

**andes.system.System.g\_update**(*self*, *models*: *collections.OrderedDict*)

Call the algebraic equation update method for models in sequence.

## Notes

Like *f\_update*, updated values have not collected into DAE at the end of the step.

`andes.system.System.j_update(self, models: collections.OrderedDict, info=None)`

Call the Jacobian update method for models in sequence.

The procedure is - Restore the sparsity pattern with `andes.variables.dae.DAE.restore_sparse()` - For each sparse matrix in (fx, fy, gx, gy), evaluate the Jacobian function calls and add values.

## Notes

Updated Jacobians are immediately reflected in the DAE sparse matrices (fx, fy, gx, gy).

### 4.1.5 Configuration

System, models and routines have a member attribute *config* for model-specific or routine-specific configurations. System manages all configs, including saving to a config file and loading back.

`andes.system.System.get_config(self)`

Collect config data from models.

#### Returns

**dict** a dict containing the config from devices; class names are keys and configs in a dict are values.

`andes.system.System.save_config(self, file_path=None, overwrite=False)`

Save all system, model, and routine configurations to an rc-formatted file.

#### Parameters

**file\_path** [str, optional] path to the configuration file default to `~/andes/andes.rc`.

**overwrite** [bool, optional] If file exists, True to overwrite without confirmation. Otherwise prompt for confirmation.

**Warning:** Saved config is loaded back and populated *at system instance creation time*. Configs from the config file takes precedence over default config values.

`andes.system.System.load_config(conf_path=None)`

Load config from an rc-formatted file.

#### Parameters

**conf\_path** [None or str] Path to the config file. If is *None*, the function body will not run.

#### Returns

`configparse.ConfigParser`

**Warning:** It is important to note that configs from files is passed to *model constructors* during instantiation. If one needs to modify config for a run, it needs to be done before instantiating `System`, or before running `andes` from command line. Directly modifying `Model.config` may not take effect or have side effect as for the current implementation.

## 4.2 Group

A group is a collection of similar functional models with common variables and parameters. It is mandatory to enforce the common variables and parameters when develop new models. The common variables and parameters are typically the interface when connecting different group models.

For example, the Group *RenGen* has variables *Pe* and *Qe*, which are active power output and reactive power output. Such common variables can be retrieved by other models, such as one in the Group *RenExciter* for further calculation.

In such a way, the same variable interface is realized so that all model in the same group could carry out similar function.

---

<code>GroupBase()</code>	Base class for groups.
--------------------------	------------------------

---

### 4.2.1 andes.models.group.GroupBase

**class** `andes.models.group.GroupBase`

Base class for groups.

`__init__()`

#### Methods

<code>add(idx, model)</code>	Register an idx from model_name to the group
<code>add_model(name, instance)</code>	Add a Model instance to group.
<code>doc([export])</code>	Return the documentation of the group in a string.
<code>doc_all([export])</code>	Return documentation of the group and its models.
<code>find_idx(keys, values[, allow_none, default])</code>	Find indices of devices that satisfy the given <i>key=value</i> condition.
<code>get(src, idx[, attr, allow_none, default])</code>	Based on the indexer, get the <i>attr</i> field of the <i>src</i> parameter or variable.
<code>get_field(src, idx, field)</code>	Helper function for retrieving an attribute of a member variable shared by models in this group.
<code>get_next_idx([idx, model_name])</code>	Get a no-conflict idx for a new device.

continues on next page

Table 2 – continued from previous page

<code>idx2model</code> (idx[, allow_none])	Find model name for the given idx.
<code>idx2uid</code> (idx)	Convert idx to the 0-indexed unique index.
<code>set</code> (src, idx, attr, value)	Set the value of an attribute of a group property.
<code>set_backref</code> (name, from_idx, to_idx)	Set idxes to BackRef, and set them to models.

**GroupBase.add**`GroupBase.add(idx, model)`

Register an idx from model\_name to the group

**Parameters****idx**: `Union[str, float, int]` Register an element to a model**model**: `Model` instance of the model**Returns****GroupBase.add\_model**`GroupBase.add_model(name: str, instance)`

Add a Model instance to group.

**Parameters****name** [str] Model name**instance** [Model] Model instance**Returns**

None

**GroupBase.doc**`GroupBase.doc(export='plain')`

Return the documentation of the group in a string.

**GroupBase.doc\_all**`GroupBase.doc_all(export='plain')`

Return documentation of the group and its models.

**Parameters****export** ['plain' or 'rest'] Export format, plain-text or RestructuredText**Returns**

str

### GroupBase.find\_idx

GroupBase.**find\_idx**(keys, values, allow\_none=False, default=None)

Find indices of devices that satisfy the given *key=value* condition.

This method iterates over all models in this group.

### GroupBase.get

GroupBase.**get**(src: str, idx, attr: str = 'v', allow\_none=False, default=0.0)

Based on the indexer, get the *attr* field of the *src* parameter or variable.

#### Parameters

**src** [str] param or var name

**idx** [array-like] device idx

**attr** The attribute of the param or var to retrieve

**allow\_none** [bool] True to allow None values in the indexer

**default** [float] If *allow\_none* is true, the default value to use for None indexer.

#### Returns

The requested param or variable attribute. If *idx* is a list, return a list of values.

If *idx* is a single element, return a single value.

### GroupBase.get\_field

GroupBase.**get\_field**(src: str, idx, field: str)

Helper function for retrieving an attribute of a member variable shared by models in this group.

#### Returns

**list** A list with the length equal to `len(idx)`.

### GroupBase.get\_next\_idx

GroupBase.**get\_next\_idx**(idx=None, model\_name=None)

Get a no-conflict idx for a new device. Use the provided *idx* if no conflict. Generate a new one otherwise.

#### Parameters

**idx** [str or None] Proposed idx. If None, assign a new one.

**model\_name** [str or None] Model name. If not, prepend the group name.

#### Returns

**str** New device name.

### GroupBase.idx2model

GroupBase.idx2model(*idx*, *allow\_none=False*)

Find model name for the given idx.

#### Parameters

**idx** [float, int, str, array-like] idx or idx-es of devices.

**allow\_none** [bool] If True, return *None* at the positions where idx is not found.

#### Returns

If *idx* is a list, return a list of model instances.

If *idx* is a single element, return a model instance.

### GroupBase.idx2uid

GroupBase.idx2uid(*idx*)

Convert idx to the 0-indexed unique index.

#### Parameters

**idx** [array-like, numbers, or str] idx of devices

#### Returns

**list** A list containing the unique indices of the devices

### GroupBase.set

GroupBase.set(*src: str*, *idx*, *attr*, *value*)

Set the value of an attribute of a group property. Performs `self.<src>.<attr>[idx] = value`.

The user needs to ensure that the property is shared by all models in this group.

#### Parameters

**src** [str] Name of property.

**idx** [str, int, float, array-like] Indices of devices.

**attr** [str, optional, default='v'] The internal attribute of the property to get. v for values, a for address, and e for equation value.

**value** [array-like] New values to be set

#### Returns

**bool** True when successful.

### GroupBase.set\_backref

GroupBase.set\_backref(*name*, *from\_idx*, *to\_idx*)

Set idxes to BackRef, and set them to models.

### Attributes

---

*class\_name*

---

*n*

Total number of devices.

---

### GroupBase.class\_name

**property** GroupBase.class\_name

### GroupBase.n

**property** GroupBase.n  
Total number of devices.

## 4.3 Models

This section introduces the modeling of power system devices. The terminology "model" is used to describe the mathematical representation of a *type* of device, such as synchronous generators or turbine governors. The terminology "device" is used to describe a particular instance of a model, for example, a specific generator.

To define a model in ANDES, two classes, `ModelData` and `Model` need to be utilized. Class `ModelData` is used for defining parameters that will be provided from input files. It provides API for adding data from devices and managing the data. Class `Model` is used for defining other non-input parameters, service variables, and DAE variables. It provides API for converting symbolic equations, storing Jacobian patterns, and updating equations.

The following classes are related to models:

<code>ModelData(*args[, three_params])</code>	Class for holding parameter data for a model.
<code>Model([system, config])</code>	Base class for power system DAE models.
<code>ModelCache()</code>	Class for caching the return value of callback functions.
<code>ModelCall()</code>	Class for storing generated function calls, Jacobian calls, and arguments.

### 4.3.1 andes.core.model.ModelData

**class** andes.core.model.**ModelData**(\*args, three\_params=True, \*\*kwargs)

Class for holding parameter data for a model.

This class is designed to hold the parameter data separately from model equations. Models should inherit this class to define the parameters from input files.

Inherit this class to create the specific class for holding input parameters for a new model. The recommended name for the derived class is the model name with Data. For example, data for *GENROU* should be named *GENROUData*.

Parameters should be defined in the `__init__` function of the derived class.

Refer to `andes.core.param` for available parameter types.

#### Notes

Three default parameters are pre-defined in `ModelData` and will be inherited by all models. They are

- `idx`, unique device idx of type `andes.core.param.DataParam`
- `u`, connection status of type `andes.core.param.NumParam`
- `name`, (device name of type `andes.core.param.DataParam`)

In rare cases one does not want to define these three parameters, one can pass `three_params=True` to the constructor of `ModelData`.

#### Examples

If we want to build a class `PQData` (for static PQ load) with three parameters,  $V_n$ ,  $p_0$  and  $q_0$ , we can use the following

```
from andes.core.model import ModelData, Model
from andes.core.param import IdxParam, NumParam

class PQData(ModelData):
    super().__init__()
    self.Vn = NumParam(default=110,
                        info="AC voltage rating",
                        unit='kV', non_zero=True,
                        tex_name=r'V_n')
    self.p0 = NumParam(default=0,
                        info='active power load in system base',
                        tex_name=r'p_0', unit='p.u.')
    self.q0 = NumParam(default=0,
                        info='reactive power load in system base',
                        tex_name=r'q_0', unit='p.u.')
```

In this example, all the three parameters are defined as `andes.core.param.NumParam`. In the full `PQData` class, other types of parameters also exist. For example, to store the idx of *owner*, `PQData` uses

```
self.owner = IdxParam(model='Owner', info="owner idx")
```

### Attributes

**cache** A cache instance for different views of the internal data.

**flags** [dict] Flags to control the routine and functions that get called. If the model is using user-defined numerical calls, set *f\_num*, *g\_num* and *j\_num* properly.

```
__init__(*args, three_params=True, **kwargs)
```

### Methods

<code>add(**kwargs)</code>	Add a device (an instance) to this model.
<code>as_df([vin])</code>	Export all parameters as a <i>pandas.DataFrame</i> object.
<code>as_dict([vin])</code>	Export all parameters as a dict.
<code>find_idx(keys, values[, allow_none, default])</code>	Find <i>idx</i> of devices whose values match the given pattern.
<code>find_param(prop)</code>	Find params with the given property and return in an <i>OrderedDict</i> .
<code>update_from_df(df[, vin])</code>	Update parameter values from a <i>DataFrame</i> .

### ModelData.add

```
ModelData.add(**kwargs)
```

Add a device (an instance) to this model.

#### Parameters

**kwargs** model parameters are collected into the kwargs dictionary

**Warning:** This function is not intended to be used directly. Use the add method from System so that the index can be registered correctly.

### ModelData.as\_df

ModelData.as\_df(*vin=False*)

Export all parameters as a *pandas.DataFrame* object. This function utilizes *as\_dict* for preparing data.

#### Returns

**DataFrame** A dataframe containing all model data. An *uid* column is added.

**vin** [bool] If True, export all parameters from original input (*vin*).

### ModelData.as\_dict

ModelData.as\_dict(*vin=False*)

Export all parameters as a dict.

#### Returns

**dict** a dict with the keys being the *ModelData* parameter names and the values being an array-like of data in the order of adding. An additional *uid* key is added with the value default to range(*n*).

### ModelData.find\_idx

ModelData.find\_idx(*keys, values, allow\_none=False, default=False*)

Find *idx* of devices whose values match the given pattern.

#### Parameters

**keys** [str, array-like, Sized] A string or an array-like of strings containing the names of parameters for the search criteria

**values** [array, array of arrays, Sized] Values for the corresponding key to search for. If *keys* is a str, *values* should be an array of elements. If *keys* is a list, *values* should be an array of arrays, each corresponds to the key.

**allow\_none** [bool, Sized] Allow key, value to be not found. Used by groups.

**default** [bool] Default *idx* to return if not found (missing)

#### Returns

**list** indices of devices

### ModelData.find\_param

ModelData.**find\_param**(prop)

Find params with the given property and return in an OrderedDict.

#### Parameters

**prop** [str] Property name

#### Returns

OrderedDict

### ModelData.update\_from\_df

ModelData.**update\_from\_df**(df, vin=False)

Update parameter values from a DataFrame.

Adding devices are not allowed.

## 4.3.2 andes.core.model.Model

**class** andes.core.model.**Model**(system=None, config=None)

Base class for power system DAE models.

After subclassing *ModelData*, subclass *Model* to complete a DAE model. Subclasses of *Model* defines DAE variables, services, and other types of parameters, in the constructor `__init__`.

### Notes

To modify parameters or services use `set()`, which writes directly to the given attribute, or `alter()`, which converts parameters to system base like that for input data.

### Examples

Take the static PQ as an example, the subclass of *Model*, *PQ*, should looks like

```
class PQ(PQData, Model):
    def __init__(self, system, config):
        PQData.__init__(self)
        Model.__init__(self, system, config)
```

Since *PQ* is calling the base class constructors, it is meant to be the final class and not further derived. It inherits from *PQData* and *Model* and must call constructors in the order of *PQData* and *Model*. If the derived class of *Model* needs to be further derived, it should only derive from *Model* and use a name ending with *Base*. See `andes.models.synchronous.GENBASE`.

Next, in *PQ.\_\_init\_\_*, set proper flags to indicate the routines in which the model will be used

```
self.flags.update({'pflow': True})
```

Currently, flags *pflow* and *tds* are supported. Both are *False* by default, meaning the model is neither used in power flow nor time-domain simulation. **A very common pitfall is forgetting to set the flag.**

Next, the group name can be provided. A group is a collection of models with common parameters and variables. Devices *idx* of all models in the same group must be unique. To provide a group name, use

```
self.group = 'StaticLoad'
```

The group name must be an existing class name in `andes.models.group`. The model will be added to the specified group and subject to the variable and parameter policy of the group. If not provided with a group class name, the model will be placed in the *Undefined* group.

Next, additional configuration flags can be added. Configuration flags for models are load-time variables specifying the behavior of a model. It can be exported to an *andes.rc* file and automatically loaded when creating the *System*. Configuration flags can be used in equation strings, as long as they are numerical values. To add config flags, use

```
self.config.add(OrderedDict((( 'pq2z', 1), )))
```

It is recommended to use *OrderedDict* instead of *dict*, although the syntax is verbose. Note that booleans should be provided as integers (1, or 0), since *True* or *False* is interpreted as a string when loaded from the *rc* file and will cause an error.

Next, it's time for variables and equations! The *PQ* class does not have internal variables itself. It uses its *bus* parameter to fetch the corresponding *a* and *v* variables of buses. Equation wise, it imposes an active power and a reactive power load equation.

To define external variables from *Bus*, use

```
self.a = ExtAlgeb(model='Bus', src='a',
                  indexer=self.bus, tex_name=r'\theta')
self.v = ExtAlgeb(model='Bus', src='v',
                  indexer=self.bus, tex_name=r'V')
```

Refer to the subsection Variables for more details.

The simplest *PQ* model will impose constant P and Q, coded as

```
self.a.e_str = "u * p"
self.v.e_str = "u * q"
```

where the *e\_str* attribute is the equation string attribute. *u* is the connectivity status. Any parameter, config, service or variables can be used in equation strings.

Three additional scalars can be used in equations: - *dae\_t* for the current simulation time can be used if the model has flag *tds*. - *sys\_f* for system frequency (from `system.config.freq`). - *sys\_mva* for system base mva (from `system.config.mva`).

The above example is overly simplified. Our *PQ* model wants a feature to switch itself to a constant impedance if the voltage is out of the range (*vmin*, *vmax*). To implement this, we need to introduce a discrete component called *Limiter*, which yields three arrays of binary flags, *zi*, *zl*, and *zu* indicating in range, below lower limit, and above upper limit, respectively.

First, create an attribute *vcmp* as a *Limiter* instance

```
self.vcmp = Limiter(u=self.v, lower=self.vmin, upper=self.vmax,
                    enable=self.config.pq2z)
```

where *self.config.pq2z* is a flag to turn this feature on or off. After this line, we can use *vcmp\_zi*, *vcmp\_zl*, and *vcmp\_zu* in other equation strings.

```
self.a.e_str = "u * (p0 * vcmp_zi + " \
               "p0 * vcmp_zl * (v ** 2 / vmin ** 2) + " \
               "p0 * vcmp_zu * (v ** 2 / vmax ** 2))"

self.v.e_str = "u * (q0 * vcmp_zi + " \
               "q0 * vcmp_zl * (v ** 2 / vmin ** 2) + "\
               "q0 * vcmp_zu * (v ** 2 / vmax ** 2))"
```

Note that *PQ.a.e\_str* can use the three variables from *vcmp* even before defining *PQ.vcmp*, as long as *PQ.vcmp* is defined, because *vcmp\_zi* is just a string literal in *e\_str*.

The two equations above implements a piecewise power injection equation. It selects the original power demand if within range, and uses the calculated power when out of range.

Finally, to let ANDES pick up the model, the model name needs to be added to *models/\_\_init\_\_.py*. Follow the examples in the *OrderedDict*, where the key is the file name, and the value is the class name.

### Attributes

**num\_params** [OrderedDict] {name: instance} of numerical parameters, including internal and external ones

**\_\_init\_\_** (*system=None*, *config=None*)

### Methods

<i>a_reset</i> ()	Reset addresses to empty and reset flags.address to False.
<i>alter</i> (src, idx, value)	Alter input parameter or service values.
<i>doc</i> ([max_width, export])	Retrieve model documentation as a string.
<i>e_clear</i> ()	Clear equation value arrays associated with all internal variables.
<i>externalize</i> ()	Externalize internal data as a snapshot.
<i>f_numeric</i> (*kwargs)	Custom fcall functions.

continues on next page

Table 6 – continued from previous page

<code>f_update()</code>	Evaluate differential equations.
<code>g_numeric(**kwargs)</code>	Custom gcall functions.
<code>g_update()</code>	Evaluate algebraic equations.
<code>get(src, idx[, attr, allow_none, default])</code>	Get the value of an attribute of a model property.
<code>get_init_order()</code>	Get variable initialization order and send to <i>logger.info</i> .
<code>get_inputs([refresh])</code>	Get an OrderedDict of the inputs to the numerical function calls.
<code>get_md5()</code>	Return the md5 hash of concatenated equation strings.
<code>get_times()</code>	Get event switch_times from <i>TimerParam</i> .
<code>idx2uid(idx)</code>	Convert idx to the 0-indexed unique index.
<code>init(routine[, debug])</code>	Numerical initialization of a model.
<code>internalize()</code>	Internalize snapshot data.
<code>j_numeric(**kwargs)</code>	Custom numeric update functions.
<code>j_update()</code>	Update Jacobian elements.
<code>l_check_eq([init])</code>	Call the <code>check_eq</code> method of discrete components to update equation-dependent flags.
<code>l_update_var(dae_t, *args[, niter, err])</code>	Call the <code>check_var</code> method of discrete components to update the internal status flags.
<code>list2array()</code>	Convert all the value attributes v to NumPy arrays.
<code>mock_refresh_inputs()</code>	Use mock data to fill the inputs.
<code>numba_jitify([parallel, cache, nopython])</code>	Convert equation residual calls, Jacobian calls, and variable service calls into JIT compiled functions.
<code>post_init_check()</code>	Post init checking.
<code>precompile()</code>	Trigger numba compilation for this model.
<code>prepare([quick, pycode_path, yapf_pycode])</code>	Symbolic processing and code generation.
<code>refresh_inputs()</code>	This is the helper function to refresh inputs.
<code>refresh_inputs_arg()</code>	Refresh inputs for each function with individual argument list.
<code>s_numeric(**kwargs)</code>	Custom service value functions.
<code>s_numeric_var(**kwargs)</code>	Custom variable service value functions.
<code>s_update()</code>	Update service equation values.
<code>s_update_post()</code>	Update post-initialization services.
<code>s_update_var()</code>	Update VarService.
<code>set(src, idx, attr, value)</code>	Set the value of an attribute of a model property.
<code>set_backref(name, from_idx, to_idx)</code>	Helper function for setting idx-es to BackRef.
<code>set_in_use()</code>	Set the <i>in_use</i> attribute.
<code>solve_iter(name, kwargs)</code>	Solve iterative initialization.
<code>solve_iter_single(name, inputs, pos)</code>	Solve iterative initialization for one given device.
<code>store_sparse_pattern()</code>	Store rows and columns of the non-zeros in the Jacobians for building the sparsity pattern.

continues on next page

Table 6 – continued from previous page

<code>switch_action(dae_t)</code>	Call the switch actions.
<code>v_numeric(**kwargs)</code>	Custom variable initialization function.

### **Model.a\_reset**

`Model.a_reset()`

Reset addresses to empty and reset flags.address to False.

### **Model.alter**

`Model.alter(src, idx, value)`

Alter input parameter or service values.

If operates on a parameter, the input should be in the same base as that in the input file. This function will convert the new value to system-base per unit.

#### **Parameters**

**src** [str] The parameter name to alter

**idx** [str, float, int] The device to alter

**value** [float] The desired value

### **Model.doc**

`Model.doc(max_width=78, export='plain')`

Retrieve model documentation as a string.

### **Model.e\_clear**

`Model.e_clear()`

Clear equation value arrays associated with all internal variables.

### **Model.externalize**

`Model.externalize()`

Externalize internal data as a snapshot.

### Model.f\_numeric

`Model.f_numeric(**kwargs)`

Custom fcall functions. Modify equations directly.

### Model.f\_update

`Model.f_update()`

Evaluate differential equations.

### Notes

In-place equations: added to the corresponding DAE array. Non-inplace equations: in-place set to internal array to overwrite old values (and avoid clearing).

### Model.g\_numeric

`Model.g_numeric(**kwargs)`

Custom gcall functions. Modify equations directly.

### Model.g\_update

`Model.g_update()`

Evaluate algebraic equations.

### Model.get

`Model.get(src: str, idx, attr: str = 'v', allow_none=False, default=0.0)`

Get the value of an attribute of a model property.

The return value is `self.<src>.<attr>[idx]`

#### Parameters

**src** [str] Name of the model property

**idx** [str, int, float, array-like] Indices of the devices

**attr** [str, optional, default='v'] The attribute of the property to get. v for values, a for address, and e for equation value.

**allow\_none** [bool] True to allow None values in the indexer

**default** [float] If *allow\_none* is true, the default value to use for None indexer.

#### Returns

**array-like** `self.<src>.<attr>[idx]`

### Model.get\_init\_order

`Model.get_init_order()`

Get variable initialization order and send to *logger.info*.

### Model.get\_inputs

`Model.get_inputs(refresh=False)`

Get an OrderedDict of the inputs to the numerical function calls.

#### Parameters

**refresh** [bool] Refresh the values in the dictionary. This is only used when the memory address of arrays changed. After initialization, all array assignments are inplace. To avoid overhead, refresh should not be used after initialization.

#### Returns

**OrderedDict** The input name and value array pairs in an OrderedDict

### Notes

*dae.t* is now a `numpy.ndarray` which has stable memory. There is no need to refresh *dat\_t* in this version.

### Model.get\_md5

`Model.get_md5()`

Return the md5 hash of concatenated equation strings.

### Model.get\_times

`Model.get_times()`

Get event switch\_times from *TimerParam*.

#### Returns

**list** A list containing all switching times defined in *TimerParams*

**Model.idx2uid****Model.idx2uid**(*idx*)Convert *idx* to the 0-indexed unique index.**Parameters****idx** [array-like, numbers, or str] *idx* of devices**Returns****list** A list containing the unique indices of the devices**Model.init****Model.init**(*routine*, *debug=False*)

Numerical initialization of a model.

Initialization sequence: 1. Sequential initialization based on the order of definition 2. Use Newton-Krylov method for iterative initialization 3. Custom init

**Model.internalize****Model.internalize**()

Internalize snapshot data.

**Model.j\_numeric****Model.j\_numeric**(\*\**kwargs*)

Custom numeric update functions.

This function should append indices to *\_ifx*, *\_jfx*, and append anonymous functions to *\_vfx*. It is only called once by *store\_sparse\_pattern*.

**Model.j\_update****Model.j\_update**()

Update Jacobian elements.

Values are stored to **Model.triplets[jname]**, where *jname* is a jacobian name.

**Returns****None**

### Model.l\_check\_eq

`Model.l_check_eq(init=False, **kwargs)`

Call the `check_eq` method of discrete components to update equation-dependent flags.

This function should be called after equation updates. AntiWindup limiters use it to append pegged states to the `x_set` list.

#### Returns

None

### Model.l\_update\_var

`Model.l_update_var(dae_t, *args, niter=None, err=None, **kwargs)`

Call the `check_var` method of discrete components to update the internal status flags.

The function is variable-dependent and should be called before updating equations.

#### Returns

None

### Model.list2array

`Model.list2array()`

Convert all the value attributes `v` to NumPy arrays.

Value attribute arrays should remain in the same address afterwards. Namely, all assignments to value array should be operated in place (e.g., with `[:]`).

### Model.mock\_refresh\_inputs

`Model.mock_refresh_inputs()`

Use mock data to fill the inputs.

This function is used to generate input data of the desired type to trigger JIT compilation.

### Model.numba\_jitify

`Model.numba_jitify(parallel=False, cache=True, nopython=False)`

Convert equation residual calls, Jacobian calls, and variable service calls into JIT compiled functions.

This function can be turned on by setting `System.config.numba` to 1.

**Warning:** This feature is experimental and does not guarantee a speed up. In fact, the program will likely end up slower due to compilation.

**Model.post\_init\_check****Model.post\_init\_check()**

Post init checking. Warns if values of *InitChecker* is not True.

**Model.precompile****Model.precompile()**

Trigger numba compilation for this model.

This function requires the system to be setup, i.e., memory allocated for storage.

**Model.prepare****Model.prepare(quick=False, pycode\_path=None, yapf\_pycode=False)**

Symbolic processing and code generation.

**Model.refresh\_inputs****Model.refresh\_inputs()**

This is the helper function to refresh inputs.

The functions collects object references into OrderedDict *self.\_input* and *self.\_input\_z*.

**Returns**

None

**Model.refresh\_inputs\_arg****Model.refresh\_inputs\_arg()**

Refresh inputs for each function with individual argument list.

**Model.s\_numeric****Model.s\_numeric(\*\*kwargs)**

Custom service value functions. Modify *Service.v* directly.

### Model.s\_numeric\_var

Model.s\_numeric\_var(\*\*kwargs)

Custom variable service value functions. Modify VarService.v directly.

This custom numerical function is evaluated at each step/iteration before equation update.

### Model.s\_update

Model.s\_update()

Update service equation values.

This function is only evaluated at initialization. Service values are updated sequentially. The v attribute of services will be assigned at a new memory address.

### Model.s\_update\_post

Model.s\_update\_post()

Update post-initialization services.

### Model.s\_update\_var

Model.s\_update\_var()

Update VarService.

### Model.set

Model.set(src, idx, attr, value)

Set the value of an attribute of a model property.

Performs `self.<src>.<attr>[idx] = value`.

#### Parameters

**src** [str] Name of the model property

**idx** [str, int, float, array-like] Indices of the devices

**attr** [str, optional, default='v'] The internal attribute of the property to get. v for values, a for address, and e for equation value.

**value** [array-like] New values to be set

#### Returns

**bool** True when successful.

**Model.set\_backref**

**Model.set\_backref**(*name, from\_idx, to\_idx*)

Helper function for setting idx-es to BackRef.

**Model.set\_in\_use**

**Model.set\_in\_use**()

Set the *in\_use* attribute. Called at the end of **System.collect\_ref**.

This function is overloaded by models with *BackRef* to disable calls when no model is referencing. Models with no back references will have internal variable addresses assigned but external addresses being empty.

For internal equations that has external variables, the row indices will be non-zeros, while the col indices will be empty, which causes an error when updating Jacobians.

Setting *self.in\_use* to False when *len(back\_ref\_instance.v) == 0* avoids this error. See COI.

**Model.solve\_iter**

**Model.solve\_iter**(*name, kwargs*)

Solve iterative initialization.

**Model.solve\_iter\_single**

**Model.solve\_iter\_single**(*name, inputs, pos*)

Solve iterative initialization for one given device.

**Model.store\_sparse\_pattern**

**Model.store\_sparse\_pattern**()

Store rows and columns of the non-zeros in the Jacobians for building the sparsity pattern.

This function converts the internal 0-indexed equation/variable address to the numerical addresses for the loaded system.

Calling sequence: For each Jacobian name, *fx*, *fy*, *gx* and *gy*, store by a) generated constant and variable Jacobians c) user-provided constant and variable Jacobians, d) user-provided block constant and variable Jacobians

## Notes

If `self.n == 0`, skipping this function will avoid appending empty lists/arrays and non-empty values, which, as a combination, is not accepted by `kvxopt.spmatrix`.

## Model.switch\_action

`Model.switch_action(dae_t)`

Call the switch actions.

### Parameters

**dae\_t** [float] Current simulation time

### Returns

None

**Warning:** Timer exported from blocks are supposed to work but have not been tested.

## Model.v\_numeric

`Model.v_numeric(**kwargs)`

Custom variable initialization function.

## Attributes

---

<code>class_name</code>	Return the class name
-------------------------	-----------------------

---

## Model.class\_name

**property** `Model.class_name`

Return the class name

### 4.3.3 andes.core.model.ModelCache

**class** `andes.core.model.ModelCache`

Class for caching the return value of callback functions.

Check `ModelCache.__dict__.keys()` for fields.

`__init__()`

## Methods

<code>add_callback(name, callback)</code>	Add a cache attribute and a callback function for updating the attribute.
<code>refresh([name])</code>	Refresh the cached values

### ModelCache.add\_callback

`ModelCache.add_callback(name: str, callback)`

Add a cache attribute and a callback function for updating the attribute.

#### Parameters

**name** [str] name of the cached function return value

**callback** [callable] callback function for updating the cached attribute

### ModelCache.refresh

`ModelCache.refresh(name=None)`

Refresh the cached values

#### Parameters

**name** [str, list, optional] name or list of cached to refresh, by default None for refreshing all

## 4.3.4 andes.core.model.ModelCall

**class** `andes.core.model.ModelCall`

Class for storing generated function calls, Jacobian calls, and arguments.

`__init__()`

## Methods

<code>append_ijv(j_full_name, ii, jj, vv)</code>	
<code>clear_ijv()</code>	
<code>zip_ijv(j_full_name)</code>	Return a zipped iterator for the rows, cols and vals for the specified matrix name.

**ModelCall.append\_ijv**

`ModelCall.append_ijv(j_full_name, ii, jj, vv)`

**ModelCall.clear\_ijv**

`ModelCall.clear_ijv()`

**ModelCall.zip\_ijv**

`ModelCall.zip_ijv(j_full_name)`

Return a zipped iterator for the rows, cols and vals for the specified matrix name.

### 4.3.5 Cache

*ModelData* uses a lightweight class `andes.core.model.ModelCache` for caching its data as a dictionary or a pandas DataFrame. Four attributes are defined in *ModelData.cache*:

- *dict*: all data in a dictionary with the parameter names as keys and *v* values as arrays.
- *dict\_in*: the same as *dict* except that the values are from *v\_in*, the original input.
- *df*: all data in a pandas DataFrame.
- *df\_in*: the same as *df* except that the values are from *v\_in*.

Other attributes can be added by registering with `cache.add_callback`.

`andes.core.model.ModelCache.add_callback(self, name: str, callback)`

Add a cache attribute and a callback function for updating the attribute.

**Parameters**

**name** [str] name of the cached function return value

**callback** [callable] callback function for updating the cached attribute

### 4.3.6 Define Voltage Ratings

If a model is connected to an AC Bus or a DC Node, namely, if `bus`, `bus1`, `node` or `node1` exists as parameter, it must provide the corresponding parameter, `Vn`, `Vn1`, `Vdcn` or `Vdcn1`, for rated voltages.

Controllers not connected to Bus or Node will have its rated voltages omitted and thus  $V_b = V_n = 1$ , unless one uses `andes.core.param.ExtParam` to retrieve the bus/node values.

As a rule of thumb, controllers not directly connected to the network shall use system-base per unit for voltage and current parameters. Controllers (such as a turbine governor) may inherit rated power from controlled models and thus power parameters will be converted consistently.

## Define a DAE Model

**class** andes.core.model.**Model**(system=None, config=None)

Base class for power system DAE models.

After subclassing *ModelData*, subclass *Model* to complete a DAE model. Subclasses of *Model* defines DAE variables, services, and other types of parameters, in the constructor `__init__`.

## Notes

To modify parameters or services use `set()`, which writes directly to the given attribute, or `alter()`, which converts parameters to system base like that for input data.

## Examples

Take the static PQ as an example, the subclass of *Model*, *PQ*, should look like

```
class PQ(PQData, Model):
    def __init__(self, system, config):
        PQData.__init__(self)
        Model.__init__(self, system, config)
```

Since *PQ* is calling the base class constructors, it is meant to be the final class and not further derived. It inherits from *PQData* and *Model* and must call constructors in the order of *PQData* and *Model*. If the derived class of *Model* needs to be further derived, it should only derive from *Model* and use a name ending with *Base*. See `andes.models.synchronous.GENBASE`.

Next, in *PQ.\_\_init\_\_*, set proper flags to indicate the routines in which the model will be used

```
self.flags.update({'pflow': True})
```

Currently, flags *pflow* and *tds* are supported. Both are *False* by default, meaning the model is neither used in power flow nor time-domain simulation. **A very common pitfall is forgetting to set the flag.**

Next, the group name can be provided. A group is a collection of models with common parameters and variables. Devices *idx* of all models in the same group must be unique. To provide a group name, use

```
self.group = 'StaticLoad'
```

The group name must be an existing class name in `andes.models.group`. The model will be added to the specified group and subject to the variable and parameter policy of the group. If not provided with a group class name, the model will be placed in the *Undefined* group.

Next, additional configuration flags can be added. Configuration flags for models are load-time variables specifying the behavior of a model. It can be exported to an *andes.rc* file and automatically loaded when creating the *System*. Configuration flags can be used in equation strings, as long as they are numerical values. To add config flags, use

```
self.config.add(OrderedDict((( 'pq2z', 1), )))
```

It is recommended to use *OrderedDict* instead of *dict*, although the syntax is verbose. Note that booleans should be provided as integers (1, or 0), since *True* or *False* is interpreted as a string when loaded from the *rc* file and will cause an error.

Next, it's time for variables and equations! The *PQ* class does not have internal variables itself. It uses its *bus* parameter to fetch the corresponding *a* and *v* variables of buses. Equation wise, it imposes an active power and a reactive power load equation.

To define external variables from *Bus*, use

```
self.a = ExtAlgeb(model='Bus', src='a',
                  indexer=self.bus, tex_name=r'\theta')
self.v = ExtAlgeb(model='Bus', src='v',
                  indexer=self.bus, tex_name=r'V')
```

Refer to the subsection Variables for more details.

The simplest *PQ* model will impose constant P and Q, coded as

```
self.a.e_str = "u * p"
self.v.e_str = "u * q"
```

where the *e\_str* attribute is the equation string attribute. *u* is the connectivity status. Any parameter, config, service or variables can be used in equation strings.

Three additional scalars can be used in equations: - *dae\_t* for the current simulation time can be used if the model has flag *tds*. - *sys\_f* for system frequency (from *system.config.freq*). - *sys\_mva* for system base mva (from *system.config.mva*).

The above example is overly simplified. Our *PQ* model wants a feature to switch itself to a constant impedance if the voltage is out of the range (*vmin*, *vmax*). To implement this, we need to introduce a discrete component called *Limiter*, which yields three arrays of binary flags, *zi*, *zl*, and *zu* indicating in range, below lower limit, and above upper limit, respectively.

First, create an attribute *vcmp* as a *Limiter* instance

```
self.vcmp = Limiter(u=self.v, lower=self.vmin, upper=self.vmax,
                    enable=self.config.pq2z)
```

where *self.config.pq2z* is a flag to turn this feature on or off. After this line, we can use *vcmp\_zi*, *vcmp\_zl*, and *vcmp\_zu* in other equation strings.

```
self.a.e_str = "u * (p0 * vcmp_zi + " \
               "p0 * vcmp_zl * (v ** 2 / vmin ** 2) + " \
               "p0 * vcmp_zu * (v ** 2 / vmax ** 2))"

self.v.e_str = "u * (q0 * vcmp_zi + " \
               "q0 * vcmp_zl * (v ** 2 / vmin ** 2) + " \
               "q0 * vcmp_zu * (v ** 2 / vmax ** 2))"
```

Note that *PQ.a.e\_str* can use the three variables from *vcmp* even before defining *PQ.vcmp*, as long as *PQ.vcmp* is defined, because *vcmp\_zi* is just a string literal in *e\_str*.

The two equations above implements a piecewise power injection equation. It selects the original power demand if within range, and uses the calculated power when out of range.

Finally, to let ANDES pick up the model, the model name needs to be added to *models/\_\_init\_\_.py*. Follow the examples in the *OrderedDict*, where the key is the file name, and the value is the class name.

### Attributes

**num\_params** [OrderedDict] {name: instance} of numerical parameters, including internal and external ones

## Dynamicity Under the Hood

The magic for automatic creation of variables are all hidden in `andes.core.model.Model.__setattr__()`, and the code is incredible simple. It sets the name, `tex_name`, and owner model of the attribute instance and, more importantly, does the book keeping. In particular, when the attribute is a `andes.core.block.Block` subclass, `__setattr__` captures the exported instances, recursively, and prepends the block name to exported ones. All these convenience owe to the dynamic feature of Python.

During the code generation phase, the symbols are created by checking the book-keeping attributes, such as *states*, *algebs*, and attributes in *Model.cache*.

In the numerical evaluation phase, *Model* provides a method, `andes.core.model.get_inputs()`, to collect the variable value arrays in a dictionary, which can be effortlessly passed as arguments to numerical functions.

### 4.3.7 Commonly Used Attributes in Models

The following *Model* attributes are commonly used for debugging. If the attribute is an *OrderedDict*, the keys are attribute names in *str*, and corresponding values are the instances.

- `params` and `params_ext`, two *OrderedDict* for internal (both numerical and non-numerical) and external parameters, respectively.
- `num_params` for numerical parameters, both internal and external.
- `states` and `algebs`, two *OrderedDict* for state variables and algebraic variables, respectively.
- `states_ext` and `algebs_ext`, two *OrderedDict* for external states and algebraics.
- `discrete`, an *OrderedDict* for discrete components.
- `blocks`, an *OrderedDict* for blocks.
- `services`, an *OrderedDict* for services with `v_str`.
- `services_ext`, an *OrderedDict* for externally retrieved services.

### 4.3.8 Attributes in *Model.cache*

Attributes in *Model.cache* are additional book-keeping structures for variables, parameters and services. The following attributes are defined.

- `all_vars`: all the variables.
- `all_vars_names`, a list of all variable names.
- `all_params`, all parameters.
- `all_params_names`, a list of all parameter names.
- `algebs_and_ext`, an *OrderedDict* of internal and external algebraic variables.
- `states_and_ext`, an *OrderedDict* of internal and external differential variables.
- `services_and_ext`, an *OrderedDict* of internal and external service variables.
- `vars_int`, an *OrderedDict* of all internal variables, states and then algebs.
- `vars_ext`, an *OrderedDict* of all external variables, states and then algebs.

### Equation Generation

`Model.syms`, an instance of `SymProcessor`, handles the symbolic to numeric generation when called. The equation generation is a multi-step process with symbol preparation, equation generation, Jacobian generation, initializer generation, and pretty print generation.

**class** `andes.core.model.SymProcessor`(*parent*)

A helper class for symbolic processing and code generation.

#### Parameters

**parent** [Model] The *Model* instance to process

#### Attributes

**xy** [sympy.Matrix] variables pretty print in the order of State, ExtState, Algeb, ExtAlgeb

**f** [sympy.Matrix] differential equations pretty print

**g** [sympy.Matrix] algebraic equations pretty print

**df** [sympy.SparseMatrix]  $df/d(xy)$  pretty print

**dg** [sympy.SparseMatrix]  $dg/d(xy)$  pretty print

**inputs\_dict** [OrderedDict] All possible symbols in equations, including variables, parameters, discrete flags, and config flags. It has the same variables as what `get_inputs()` returns.

**vars\_dict** [OrderedDict] variable-only symbols, which are useful when getting the Jacobian matrices.

**generate\_equations()**

Generate equations.

The pretty-print equations in matrices can be accessed in `self.f_matrix` and `self.g_matrix`.

**generate\_init()**

Generate initialization equations.

**generate\_jacobians(*diag\_eps=1e-08*)**

Generate Jacobians and store to corresponding triplets.

The internal indices of equations and variables are stored, alongside the lambda functions.

For example, `dg/dy` is a sparse matrix whose elements are (`row`, `col`, `val`), where `row` and `col` are the internal indices, and `val` is the numerical lambda function. They will be stored to

`row -> self.calls._igy col -> self.calls._jgy val -> self.calls._vgy`

**generate\_symbols()**

Generate symbols for symbolic equation generations.

This function should run before other generate equations.

**Attributes**

**inputs\_dict** [OrderedDict] name-symbol pair of all parameters, variables and configs

**vars\_dict** [OrderedDict] name-symbol pair of all variables, in the order of (`states_and_ext` + `algebs_and_ext`)

Next, function `generate_equation` converts each DAE equation set to one numerical function calls and store it in `Model.calls`. The attributes for differential equation set and algebraic equation set are `f` and `g`. Differently, service variables will be generated one by one and store in an `OrderedDict` in `Model.calls.s`.

**Jacobian Storage****4.3.9 Abstract Jacobian Storage**

Using the `.jacobian` method on `sympy.Matrix`, the symbolic Jacobians can be easily obtained. The complexity lies in the storage of the Jacobian elements. Observed that the Jacobian equation generation happens before any system is loaded, thus only the variable indices in the variable array is available. For each non-zero item in each Jacobian matrix, ANDES stores the equation index, variable index, and the Jacobian value (either a constant number or a callable function returning an array).

Note that, again, a non-zero entry in a Jacobian matrix can be either a constant or an expression. For efficiency, constant numbers and lambdified callables are stored separately. Constant numbers, therefore, can be loaded into the sparse matrix pattern when a particular system is given.

**Warning:** Data structure for the Jacobian storage has changed. Pending documentation update. Please check `andes.core.common.JacTriplet` class for more details.

The triplets, the equation (row) index, variable (column) index, and values (constant numbers or callable) are stored in `Model` attributes with the name of `_{i, j, v}{Jacobian Name}{c or None}`, where `{i, j, v}` is a single character for row, column or value, `{Jacobian Name}` is a two-character Jacobian name chosen from `fx`, `fy`, `gx`, and `gy`, and `{c or None}` is either character `c` or no character, indicating whether it corresponds to the constants or non-constants in the Jacobian.

For example, the triplets for the constants in Jacobian `gy` are stored in `_igyc`, `_jgyc`, and `_vgyc`.

In terms of the non-constant entries in Jacobians, the callable functions are stored in the corresponding `_v{Jacobian Name}` array. Note the differences between, for example, `_vgy` and `_vgyc`: `_vgy` is a list of callables, while `_vgyc` is a list of constant numbers.

### 4.3.10 Concrete Jacobian Storage

When a specific system is loaded and the addresses are assigned to variables, the abstract Jacobian triplets, more specifically, the rows and columns, are replaced with the array of addresses. The new addresses and values will be stored in `Model` attributes with the names `{i, j, v}{Jacobian Name}{c or None}`. Note that there is no underscore for the concrete Jacobian triplets.

For example, if model `PV` has a list of variables `[p, q, a, v]`. The equation associated with `p` is  $-u * p_0$ , and the equation associated with `q` is  $u * (v_0 - v)$ . Therefore, the derivative of equation  $v_0 - v$  over `v` is  $-u$ . Note that `u` is unknown at generation time, thus the value is NOT a constant and should go `vgy`.

The values in `_igy`, `_jgy` and `_vgy` contains, respectively, 1, 3, and a lambda function which returns  $-u$ .

When a specific system is loaded, for example, a 5-bus system, the addresses for the `q` and `v` are `[11, 13, 15, and [5, 7, 9]`. `PV.igy` and `PV.jgy` will thus query the corresponding address list based on `PV._igy` and `PV._jgy` and store `[11, 13, 15, and [5, 7, 9]`.

## Initialization

Value providers such as services and DAE variables need to be initialized. Services are initialized before any DAE variable. Both Services and DAE Variables are initialized *sequentially* in the order of declaration.

Each Service, in addition to the standard `v_str` for symbolic initialization, provides a `v_numeric` hook for specifying a custom function for initialization. Custom initialization functions for DAE variables, are lumped in a single function in `Model.v_numeric`.

ANDES has an *experimental* Newton-Krylov method based iterative initialization. All DAE variables with `v_iter` will be initialized using the iterative approach

## Additional Numerical Equations

Addition numerical equations are allowed to complete the "hybrid symbolic-numeric" framework. Numerical function calls are useful when the model DAE is non-standard or hard to be generalized. Since the symbolic-to-numeric generation is an additional layer on top of the numerical simulation, it is fundamentally the same as user-provided numerical function calls.

ANDES provides the following hook functions in each `Model` subclass for custom numerical functions:

- `v_numeric`: custom initialization function
- `s_numeric`: custom service value function
- `g_numeric`: custom algebraic equations; update the `e` of the corresponding variable.
- `f_numeric`: custom differential equations; update the `e` of the corresponding variable.
- `j_numeric`: custom Jacobian equations; the function should append to `_i`, `_j` and `_v` structures.

For most models, numerical function calls are unnecessary and not recommended as it increases code complexity. However, when the data structure or the DAE are difficult to generalize in the symbolic framework, the numerical equations can be used.

For interested readers, see the COI symbolic implementation which calculated the center-of-inertia speed of generators. The COI could have been implemented numerically with for loops instead of `NumReduce`, `NumRepeat` and external variables.

## 4.4 Atomic Types

ANDES contains three types of atom classes for building DAE models. These types are parameter, variable and service.

### 4.4.1 Value Provider

Before addressing specific atom classes, the terminology *v-provider*, and *e-provider* are discussed. A value provider class (or *v-provider* for short) references any class with a member attribute named `v`, which should be a list or a 1-dimensional array of values. For example, all parameter classes are v-providers, since a parameter class should provide values for that parameter.

---

**Note:** In fact, all types of atom classes are v-providers, meaning that an instance of an atom class must contain values.

---

The values in the `v` attribute of a particular instance are values that will substitute the instance for computation. If in a model, one has a parameter

```
self.v0 = NumParam()
self.b = NumParam()
```

(continues on next page)

(continued from previous page)

```
# where self.v0.v = np.array([1., 1.05, 1.1]
# and self.b.v = np.array([10., 10., 10.]
```

Later, this parameter is used in an equation, such as

```
self.v = ExtAlgeb(model='Bus', src='v',
                  indexer=self.bus,
                  e_str='v0 **2 * b')
```

While computing  $v0 ** 2 * b$ ,  $v0$  and  $b$  will be substituted with the values in *self.v0.v* and *self.b.v*.

Sharing this interface  $v$  allows interoperability among parameters and variables and services. In the above example, if one defines  $v0$  as a *ConstService* instance, such as

```
self.v0 = ConstService(v_str='1.0')
```

Calculations will still work without modification.

## 4.4.2 Equation Provider

Similarly, an equation provider class (or *e-provider*) references any class with a member attribute named *e*, which should be a 1-dimensional array of values. The values in the *e* array are the results from the equation and will be summed to the numerical DAE at the addresses specified by the attribute *a*.

---

**Note:** Currently, only variables are *e-provider* types.

---

If a model has an external variable that links to *Bus.v* (voltage), such as

```
self.v = ExtAlgeb(model='Bus', src='v',
                  indexer=self.bus,
                  e_str='v0 **2 * b')
```

The addresses of the corresponding voltage variables will be retrieved into *self.v.a*, and the equation evaluation results will be stored in *self.v.e*

## 4.5 Parameters

### 4.5.1 Background

Parameter is a type of building atom for DAE models. Most parameters are read directly from an input file and passed to equation, and other parameters can be calculated from existing parameters.

The base class for parameters in ANDES is *BaseParam*, which defines interfaces for adding values and checking the number of values. *BaseParam* has its values stored in a plain list, the member attribute *v*. Subclasses such as *NumParam* stores values using a NumPy ndarray.

An overview of supported parameters is given below.

<i>BaseParam</i> ([default, name, tex_name, info, ...])	The base parameter class.
<i>DataParam</i> ([default, name, tex_name, info, ...])	An alias of the <i>BaseParam</i> class.
<i>IdxParam</i> ([default, name, tex_name, info, ...])	An alias of <i>BaseParam</i> with an additional storage of the owner model name
<i>NumParam</i> (default, str, ...)	A computational numerical parameter.
<i>ExtParam</i> (model, src[, indexer, vtype, ...])	A parameter whose values are retrieved from an external model or group.
<i>TimerParam</i> ([callback, default, name, ...])	A parameter whose values are event occurrence times during the simulation.

### andes.core.param.BaseParam

```
class andes.core.param.BaseParam(default: Optional[Union[float, str, int]] = None, name:
    Optional[str] = None, tex_name: Optional[str] = None, info:
    Optional[str] = None, unit: Optional[str] = None, mandatory:
    bool = False, export: bool = True, iconvert: Optional[Callable]
    = None, oconvert: Optional[Callable] = None)
```

The base parameter class.

This class provides the basic data structure and interfaces for all types of parameters. Parameters are from input files and in general constant once initialized.

Subclasses should overload the *n()* method for the total count of elements in the value array.

#### Parameters

**default** [str or float, optional] The default value of this parameter if None is provided

**name** [str, optional] Parameter name. If not provided, it will be automatically set to the attribute name defined in the owner model.

**tex\_name** [str, optional] LaTeX-formatted parameter name. If not provided, *tex\_name* will be assigned the same as *name*.

**info** [str, optional] Descriptive information of parameter

**mandatory** [bool] True if this parameter is mandatory

**export** [bool] True if the parameter will be exported when dumping data into files. True for most parameters. False for **BackRef**.

#### Other Parameters

**iconvert** [Callable] Converter to be applied to input data when a device is being added.

**oconvert** [callable] Converter to be applied to internal data when outputting.

**Warning:** The most distinct feature of BaseParam, DataParam and IdxParam is that values are stored in a list without conversion to array. BaseParam, DataParam or IdxParam are **not allowed** in equations.

### Attributes

**v** [list] A list holding all the values. The BaseParam class does not convert the v attribute into NumPy arrays.

**property** [dict] A dict containing the truth values of the model properties.

**\_\_init\_\_**(default: *Optional[Union[float, str, int]] = None*, name: *Optional[str] = None*, tex\_name: *Optional[str] = None*, info: *Optional[str] = None*, unit: *Optional[str] = None*, mandatory: *bool = False*, export: *bool = True*, iconvert: *Optional[Callable] = None*, oconvert: *Optional[Callable] = None*)

### Methods

<code>add([value])</code>	Add a new parameter value (from a new device of the owner model) to the v list.
<code>get_names()</code>	Return <code>self.name</code> in a list.
<code>get_property(property_name)</code>	Check the boolean value of the given property.
<code>set(pos, attr, value)</code>	Set attributes of the BaseParam class to new values at the given positions.
<code>set_all(attr, value)</code>	Set attributes of the BaseParam class to new values for all positions.

### BaseParam.add

BaseParam.add(value=None)

Add a new parameter value (from a new device of the owner model) to the v list.

### Parameters

**value** [str or float, optional] Parameter value of the new element. If None, the default will be used.

## Notes

If the value is `math.nan`, it will set to `None`.

## BaseParam.get\_names

`BaseParam.get_names()`

Return `self.name` in a list.

This is a helper function to provide the same API as blocks or discrete components.

### Returns

**list** A list only containing the name of the parameter

## BaseParam.get\_property

`BaseParam.get_property(property_name: str)`

Check the boolean value of the given property. If the property does not exist in the dictionary, `False` will be returned.

### Parameters

**property\_name** [str] Property name

### Returns

**The truth value of the property.**

## BaseParam.set

`BaseParam.set(pos, attr, value)`

Set attributes of the `BaseParam` class to new values at the given positions.

### Parameters

**pos** [int, list of integers] Positions in arrays where the values should be set

**attr** ['v', 'vin'] Name of the attribute to be set

**value** [str, float or list of above] New values

## BaseParam.set\_all

BaseParam.set\_all(attr, value)

Set attributes of the BaseParam class to new values for all positions.

### Parameters

**attr** ['v', 'vin'] Name of the attribute to be set

**value** [list of str, float or int] New values

## Attributes

<i>class_name</i>	Return the class name.
<i>n</i>	Return the count of elements in the value array.

## BaseParam.class\_name

**property** BaseParam.class\_name

Return the class name.

## BaseParam.n

**property** BaseParam.n

Return the count of elements in the value array.

## andes.core.param.DataParam

```
class andes.core.param.DataParam(default: Optional[Union[float, str, int]] = None, name:
                                Optional[str] = None, tex_name: Optional[str] = None, info:
                                Optional[str] = None, unit: Optional[str] = None, mandatory:
                                bool = False, export: bool = True, iconvert: Optional[Callable]
                                = None, oconvert: Optional[Callable] = None)
```

An alias of the *BaseParam* class.

This class is used for string parameters or non-computational numerical parameters. This class does not provide a *to\_array* method. All input values will be stored in *v* as a list.

**See also:**

***andes.core.param.BaseParam*** Base parameter class

```
__init__(default: Optional[Union[float, str, int]] = None, name: Optional[str] = None, tex_name:
Optional[str] = None, info: Optional[str] = None, unit: Optional[str] = None,
mandatory: bool = False, export: bool = True, iconvert: Optional[Callable] = None,
oconvert: Optional[Callable] = None)
```

## Methods

<code>add([value])</code>	Add a new parameter value (from a new device of the owner model) to the v list.
<code>get_names()</code>	Return <code>self.name</code> in a list.
<code>get_property(property_name)</code>	Check the boolean value of the given property.
<code>set(pos, attr, value)</code>	Set attributes of the BaseParam class to new values at the given positions.
<code>set_all(attr, value)</code>	Set attributes of the BaseParam class to new values for all positions.

## DataParam.add

`DataParam.add(value=None)`

Add a new parameter value (from a new device of the owner model) to the v list.

### Parameters

**value** [str or float, optional] Parameter value of the new element. If None, the default will be used.

## Notes

If the value is `math.nan`, it will set to None.

## DataParam.get\_names

`DataParam.get_names()`

Return `self.name` in a list.

This is a helper function to provide the same API as blocks or discrete components.

### Returns

**list** A list only containing the name of the parameter

## DataParam.get\_property

`DataParam.get_property(property_name: str)`

Check the boolean value of the given property. If the property does not exist in the dictionary, False will be returned.

### Parameters

**property\_name** [str] Property name

### Returns

The truth value of the property.

### **DataParam.set**

`DataParam.set(pos, attr, value)`

Set attributes of the BaseParam class to new values at the given positions.

#### **Parameters**

**pos** [int, list of integers] Positions in arrays where the values should be set

**attr** ['v', 'vin'] Name of the attribute to be set

**value** [str, float or list of above] New values

### **DataParam.set\_all**

`DataParam.set_all(attr, value)`

Set attributes of the BaseParam class to new values for all positions.

#### **Parameters**

**attr** ['v', 'vin'] Name of the attribute to be set

**value** [list of str, float or int] New values

### **Attributes**

---

<i>class_name</i>	Return the class name.
<i>n</i>	Return the count of elements in the value array.

---

### **DataParam.class\_name**

**property** `DataParam.class_name`

Return the class name.

## DataParam.n

### property DataParam.n

Return the count of elements in the value array.

## andes.core.param.IdxParam

```
class andes.core.param.IdxParam(default: Optional[Union[float, str, int]] = None, name:
    Optional[str] = None, tex_name: Optional[str] = None, info:
    Optional[str] = None, unit: Optional[str] = None, mandatory:
    bool = False, unique: bool = False, export: bool = True, model:
    Optional[str] = None, iconvert: Optional[Callable] = None,
    oconvert: Optional[Callable] = None)
```

An alias of *BaseParam* with an additional storage of the owner model name

This class is intended for storing *idx* into other models. It can be used in the future for data consistency check.

## Notes

This will be useful when, for example, one connects two TGs to one SynGen.

## Examples

A PQ model connected to Bus model will have the following code

```
class PQModel(...):
    def __init__(...):
        ...
        self.bus = IdxParam(model='Bus')
```

```
__init__(default: Optional[Union[float, str, int]] = None, name: Optional[str] = None, tex_name:
    Optional[str] = None, info: Optional[str] = None, unit: Optional[str] = None,
    mandatory: bool = False, unique: bool = False, export: bool = True, model:
    Optional[str] = None, iconvert: Optional[Callable] = None, oconvert:
    Optional[Callable] = None)
```

## Methods

<code>add([value])</code>	Add a new parameter value (from a new device of the owner model) to the v list.
<code>get_names()</code>	Return <code>self.name</code> in a list.
<code>get_property(property_name)</code>	Check the boolean value of the given property.
<code>set(pos, attr, value)</code>	Set attributes of the BaseParam class to new values at the given positions.
<code>set_all(attr, value)</code>	Set attributes of the BaseParam class to new values for all positions.

### IdxParam.add

`IdxParam.add(value=None)`

Add a new parameter value (from a new device of the owner model) to the v list.

#### Parameters

**value** [str or float, optional] Parameter value of the new element. If None, the default will be used.

## Notes

If the value is `math.nan`, it will set to None.

### IdxParam.get\_names

`IdxParam.get_names()`

Return `self.name` in a list.

This is a helper function to provide the same API as blocks or discrete components.

#### Returns

**list** A list only containing the name of the parameter

### IdxParam.get\_property

`IdxParam.get_property(property_name: str)`

Check the boolean value of the given property. If the property does not exist in the dictionary, False will be returned.

#### Parameters

**property\_name** [str] Property name

#### Returns

The truth value of the property.

### **IdxParam.set**

**IdxParam.set**(*pos*, *attr*, *value*)

Set attributes of the BaseParam class to new values at the given positions.

#### **Parameters**

**pos** [int, list of integers] Positions in arrays where the values should be set

**attr** ['v', 'vin'] Name of the attribute to be set

**value** [str, float or list of above] New values

### **IdxParam.set\_all**

**IdxParam.set\_all**(*attr*, *value*)

Set attributes of the BaseParam class to new values for all positions.

#### **Parameters**

**attr** ['v', 'vin'] Name of the attribute to be set

**value** [list of str, float or int] New values

### **Attributes**

<i>class_name</i>	Return the class name.
<i>n</i>	Return the count of elements in the value array.

### **IdxParam.class\_name**

**property** **IdxParam.class\_name**

Return the class name.

## IdxParam.n

### property IdxParam.n

Return the count of elements in the value array.

## andes.core.param.NumParam

```
class andes.core.param.NumParam(default: typing.Optional[typing.Union[float, str,
    typing.Callable]] = None, name: typing.Optional[str] = None,
    tex_name: typing.Optional[str] = None, info:
    typing.Optional[str] = None, unit: typing.Optional[str] = None,
    vrange: typing.Optional[typing.Union[typing.List,
    typing.Tuple]] = None, vtype: typing.Optional[typing.Type] =
    <class 'float'>, iconvert: typing.Optional[typing.Callable] =
    None, oconvert: typing.Optional[typing.Callable] = None,
    non_zero: bool = False, non_positive: bool = False,
    non_negative: bool = False, mandatory: bool = False, power:
    bool = False, ipower: bool = False, voltage: bool = False,
    current: bool = False, z: bool = False, y: bool = False, r: bool =
    False, g: bool = False, dc_voltage: bool = False, dc_current:
    bool = False, export: bool = True)
```

A computational numerical parameter.

Parameters defined using this class will have their *v* field converted to a NumPy array after adding.

The original input values will be copied to *vin*, and the system-base per-unit conversion coefficients (through multiplication) will be stored in *pu\_coeff*.

### Parameters

**default** [str or float, optional] The default value of this parameter if no value is provided

**name** [str, optional] Name of this parameter. If not provided, *name* will be set to the attribute name of the owner model.

**tex\_name** [str, optional] LaTeX-formatted parameter name. If not provided, *tex\_name* will be assigned the same as *name*.

**info** [str, optional] A description of this parameter

**mandatory** [bool] True if this parameter is mandatory

**unit** [str, optional] Unit of the parameter

**vrange** [list, tuple, optional] Typical value range

**vtype** [type, optional] Type of the *v* field. The default is `float`.

### Other Parameters

**Sn** [str] Name of the parameter for the device base power.

**Vn** [str] Name of the parameter for the device base voltage.

**non\_zero** [bool] True if this parameter must be non-zero. *non\_zero* can be combined with *non\_positive* or *non\_negative*.

**non\_positive** [bool] True if this parameter must be non-positive.

**non\_negative** [bool] True if this parameter must be non-negative.

**mandatory** [bool] True if this parameter must not be None.

**power** [bool] True if this parameter is a power per-unit quantity under the device base.

**iconvert** [callable] Callable to convert input data from excel or others to the internal *v* field.

**oconvert** [callable] Callable to convert input data from internal type to a serializable type.

**ipower** [bool] True if this parameter is an inverse-power per-unit quantity under the device base.

**voltage** [bool] True if the parameter is a voltage pu quantity under the device base.

**current** [bool] True if the parameter is a current pu quantity under the device base.

**z** [bool] True if the parameter is an AC impedance pu quantity under the device base.

**y** [bool] True if the parameter is an AC admittance pu quantity under the device base.

**r** [bool] True if the parameter is a DC resistance pu quantity under the device base.

**g** [bool] True if the parameter is a DC conductance pu quantity under the device base.

**dc\_current** [bool] True if the parameter is a DC current pu quantity under device base.

**dc\_voltage** [bool] True if the parameter is a DC voltage pu quantity under device base.

```
__init__(default: typing.Optional[typing.Union[float, str, typing.Callable]] = None, name:
typing.Optional[str] = None, tex_name: typing.Optional[str] = None, info:
typing.Optional[str] = None, unit: typing.Optional[str] = None, vrange:
typing.Optional[typing.Union[typing.List, typing.Tuple]] = None, vtype:
typing.Optional[typing.Type] = <class 'float'>, iconvert:
typing.Optional[typing.Callable] = None, oconvert: typing.Optional[typing.Callable] =
None, non_zero: bool = False, non_positive: bool = False, non_negative: bool = False,
mandatory: bool = False, power: bool = False, ipower: bool = False, voltage: bool =
False, current: bool = False, z: bool = False, y: bool = False, r: bool = False, g: bool =
False, dc_voltage: bool = False, dc_current: bool = False, export: bool = True)
```

## Methods

<code>add([value])</code>	Add a value to the parameter value list.
<code>get_names()</code>	Return <code>self.name</code> in a list.
<code>get_property(property_name)</code>	Check the boolean value of the given property.
<code>restore()</code>	Restore parameter to the original input by copying <code>self.vin</code> to <code>self.v</code> .
<code>set(pos, attr, value)</code>	Set attributes of the BaseParam class to new values at the given positions.
<code>set_all(attr, value)</code>	Set attributes of the BaseParam class to new values for all positions.
<code>set_pu_coeff(coeff)</code>	Store p.u.
<code>to_array()</code>	Converts field <code>v</code> to the NumPy array type.

## NumParam.add

`NumParam.add(value=None)`

Add a value to the parameter value list.

In addition to `BaseParam.add`, this method checks for non-zero property and reset to default if is zero.

**See also:**

[`BaseParam.add`](#) the add method of BaseParam

## NumParam.get\_names

`NumParam.get_names()`

Return `self.name` in a list.

This is a helper function to provide the same API as blocks or discrete components.

### Returns

**list** A list only containing the name of the parameter

## NumParam.get\_property

`NumParam.get_property(property_name: str)`

Check the boolean value of the given property. If the property does not exist in the dictionary, False will be returned.

### Parameters

**property\_name** [str] Property name

### Returns

The truth value of the property.

### NumParam.restore

**NumParam.restore()**

Restore parameter to the original input by copying `self.vin` to `self.v`.

*pu\_coeff* will not be overwritten.

### NumParam.set

**NumParam.set(pos, attr, value)**

Set attributes of the BaseParam class to new values at the given positions.

#### Parameters

**pos** [int, list of integers] Positions in arrays where the values should be set

**attr** ['v', 'vin'] Name of the attribute to be set

**value** [str, float or list of above] New values

### NumParam.set\_all

**NumParam.set\_all(attr, value)**

Set attributes of the BaseParam class to new values for all positions.

#### Parameters

**attr** ['v', 'vin'] Name of the attribute to be set

**value** [list of str, float or int] New values

### NumParam.set\_pu\_coeff

**NumParam.set\_pu\_coeff(coeff)**

Store p.u. conversion coefficient into `self.pu_coeff` and calculate the system-base per unit with `self.v = self.vin * self.pu_coeff`.

This function must be called after `self.to_array`.

#### Parameters

**coeff** [np.ndarray] An array with the pu conversion coefficients

## NumParam.to\_array

NumParam.**to\_array**()

Converts field *v* to the NumPy array type. to enable array-based calculation.

Must be called after adding all elements. Store a copy of original input values to field *vin*. Set *pu\_coeff* to all ones.

**Warning:** After this call, *add* will not be allowed to avoid unexpected issues.

## Attributes

<i>class_name</i>	Return the class name.
<i>n</i>	Return the count of elements in the value array.

## NumParam.class\_name

**property** NumParam.**class\_name**

Return the class name.

## NumParam.n

**property** NumParam.**n**

Return the count of elements in the value array.

## andes.core.param.ExtParam

**class** andes.core.param.**ExtParam**(*model*: str, *src*: str, *indexer*=None, *vtype*=<class 'float'>, *allow\_none*=False, *default*=0.0, *\*\*kwargs*)

A parameter whose values are retrieved from an external model or group.

### Parameters

**model** [str] Name of the model or group providing the original parameter

**src** [str] The source parameter name

**indexer** [BaseParam] A parameter defined in the model defining this ExtParam instance. *indexer.v* should contain indices into *model.src.v*. If is None, the source parameter values will be fully copied. If *model* is a group name, the indexer cannot be None.

**vtype** [type, optional, default to float] Type of each element to be retrieved. Can be str if the ExtParam is used to access an IdxParam.

## Attributes

**parent\_model** [Model] The parent model providing the original parameter.

**\_\_init\_\_**(*model: str, src: str, indexer=None, vtype=<class 'float'>, allow\_none=False, default=0.0, \*\*kwargs*)

## Methods

<code>add([value])</code>	ExtParam has an empty <i>add</i> method.
<code>get_names()</code>	Return <code>self.name</code> in a list.
<code>get_property(property_name)</code>	Check the boolean value of the given property.
<code>link_external(ext_model)</code>	Update parameter values provided by external models.
<code>restore()</code>	ExtParam has an empty <i>restore</i> method
<code>set(pos, attr, value)</code>	Set attributes of the BaseParam class to new values at the given positions.
<code>set_all(attr, value)</code>	Set attributes of the BaseParam class to new values for all positions.
<code>set_pu_coeff(coeff)</code>	Store p.u.
<code>to_array()</code>	Convert to array when <code>d_type</code> is not <code>str</code>

## ExtParam.add

ExtParam.**add**(*value=None*)

ExtParam has an empty *add* method.

## ExtParam.get\_names

ExtParam.**get\_names**()

Return `self.name` in a list.

This is a helper function to provide the same API as blocks or discrete components.

## Returns

**list** A list only containing the name of the parameter

### ExtParam.get\_property

ExtParam.**get\_property**(*property\_name: str*)

Check the boolean value of the given property. If the property does not exist in the dictionary, False will be returned.

#### Parameters

**property\_name** [str] Property name

#### Returns

The truth value of the property.

### ExtParam.link\_external

ExtParam.**link\_external**(*ext\_model*)

Update parameter values provided by external models. This needs to be called before pu conversion.

#### Parameters

**ext\_model** [Model, Group] Instance of the parent model or group, provided by the System calling this method.

### ExtParam.restore

ExtParam.**restore**()

ExtParam has an empty *restore* method

### ExtParam.set

ExtParam.**set**(*pos, attr, value*)

Set attributes of the BaseParam class to new values at the given positions.

#### Parameters

**pos** [int, list of integers] Positions in arrays where the values should be set

**attr** ['v', 'vin'] Name of the attribute to be set

**value** [str, float or list of above] New values

### ExtParam.set\_all

ExtParam.**set\_all**(*attr*, *value*)

Set attributes of the BaseParam class to new values for all positions.

#### Parameters

**attr** ['v', 'vin'] Name of the attribute to be set

**value** [list of str, float or int] New values

### ExtParam.set\_pu\_coeff

ExtParam.**set\_pu\_coeff**(*coeff*)

Store p.u. conversion coefficient into `self.pu_coeff` and calculate the system-base per unit with `self.v = self.vin * self.pu_coeff`.

This function must be called after `self.to_array`.

#### Parameters

**coeff** [np.ndarray] An array with the pu conversion coefficients

### ExtParam.to\_array

ExtParam.**to\_array**()

Convert to array when `d_type` is not str

### Attributes

<i>class_name</i>	Return the class name.
<i>n</i>	Return the count of elements in the value array.

### ExtParam.class\_name

**property** ExtParam.**class\_name**

Return the class name.

## ExtParam.n

### property ExtParam.n

Return the count of elements in the value array.

## andes.core.param.TimerParam

```
class andes.core.param.TimerParam(callback: Optional[Callable] = None, default:
    Optional[Union[float, str, Callable]] = None, name:
    Optional[str] = None, tex_name: Optional[str] = None, info:
    Optional[str] = None, unit: Optional[str] = None, non_zero:
    bool = False, mandatory: bool = False, export: bool = True)
```

A parameter whose values are event occurrence times during the simulation.

The constructor takes an additional Callable *self.callback* for the action of the event. *TimerParam* has a default value of -1, meaning deactivated.

## Examples

A connectivity status toggler class *Toggler* takes a parameter *t* for the toggle time. Inside *Toggler.\_\_init\_\_*, one would have

```
self.t = TimerParam()
```

The *Toggler* class also needs to define a method for toggling the connectivity status

```
def _u_switch(self, is_time: np.ndarray):
    action = False
    for i in range(self.n):
        if is_time[i] and (self.u.v[i] == 1):
            instance = self.system.__dict__[self.model.v[i]]
            # get the original status and flip the value
            u0 = instance.get(src='u', attr='v', idx=self.dev.v[i])
            instance.set(src='u',
                        attr='v',
                        idx=self.dev.v[i],
                        value=1-u0)
        action = True
    return action
```

Finally, in *Toggler.\_\_init\_\_*, assign the function as the callback for *self.t*

```
self.t.callback = self._u_switch
```

```
__init__(callback: Optional[Callable] = None, default: Optional[Union[float, str, Callable]] =
None, name: Optional[str] = None, tex_name: Optional[str] = None, info: Optional[str]
= None, unit: Optional[str] = None, non_zero: bool = False, mandatory: bool = False,
export: bool = True)
```

## Methods

<code>add([value])</code>	Add a value to the parameter value list.
<code>get_names()</code>	Return <code>self.name</code> in a list.
<code>get_property(property_name)</code>	Check the boolean value of the given property.
<code>is_time(dae_t)</code>	Element-wise check if the DAE time is the same as the parameter value.
<code>restore()</code>	Restore parameter to the original input by copying <code>self.vin</code> to <code>self.v</code> .
<code>set(pos, attr, value)</code>	Set attributes of the BaseParam class to new values at the given positions.
<code>set_all(attr, value)</code>	Set attributes of the BaseParam class to new values for all positions.
<code>set_pu_coeff(coeff)</code>	Store p.u.
<code>to_array()</code>	Converts field <code>v</code> to the NumPy array type.

## TimerParam.add

`TimerParam.add(value=None)`

Add a value to the parameter value list.

In addition to `BaseParam.add`, this method checks for non-zero property and reset to default if is zero.

**See also:**

[`BaseParam.add`](#) the add method of BaseParam

## TimerParam.get\_names

`TimerParam.get_names()`

Return `self.name` in a list.

This is a helper function to provide the same API as blocks or discrete components.

### Returns

**list** A list only containing the name of the parameter

### TimerParam.get\_property

TimerParam.**get\_property**(*property\_name: str*)

Check the boolean value of the given property. If the property does not exist in the dictionary, False will be returned.

#### Parameters

**property\_name** [str] Property name

#### Returns

The truth value of the property.

### TimerParam.is\_time

TimerParam.**is\_time**(*dae\_t*)

Element-wise check if the DAE time is the same as the parameter value. The current implementation uses *np.equal*.

#### Parameters

**dae\_t** [float] Current simulation time

#### Returns

**np.ndarray** The array containing the truth value of if the DAE time is close to the parameter value.

### Notes

The previous implementation with *np.isclose* with default *rtol=1e-5* mistakes the immediate pre- and post-event time as in-event when simulation time is greater than 10.

### TimerParam.restore

TimerParam.**restore**()

Restore parameter to the original input by copying *self.vin* to *self.v*.

*pu\_coeff* will not be overwritten.

### TimerParam.set

TimerParam.**set**(*pos*, *attr*, *value*)

Set attributes of the BaseParam class to new values at the given positions.

#### Parameters

**pos** [int, list of integers] Positions in arrays where the values should be set

**attr** ['v', 'vin'] Name of the attribute to be set

**value** [str, float or list of above] New values

### TimerParam.set\_all

TimerParam.**set\_all**(*attr*, *value*)

Set attributes of the BaseParam class to new values for all positions.

#### Parameters

**attr** ['v', 'vin'] Name of the attribute to be set

**value** [list of str, float or int] New values

### TimerParam.set\_pu\_coeff

TimerParam.**set\_pu\_coeff**(*coeff*)

Store p.u. conversion coefficient into `self.pu_coeff` and calculate the system-base per unit with `self.v = self.vin * self.pu_coeff`.

This function must be called after `self.to_array`.

#### Parameters

**coeff** [np.ndarray] An array with the pu conversion coefficients

### TimerParam.to\_array

TimerParam.**to\_array**()

Converts field `v` to the NumPy array type. to enable array-based calculation.

Must be called after adding all elements. Store a copy of original input values to field `vin`. Set `pu_coeff` to all ones.

**Warning:** After this call, *add* will not be allowed to avoid unexpected issues.

## Attributes

<i>class_name</i>	Return the class name.
<i>n</i>	Return the count of elements in the value array.

### TimerParam.class\_name

**property** TimerParam.class\_name  
Return the class name.

### TimerParam.n

**property** TimerParam.n  
Return the count of elements in the value array.

## 4.6 Variables

DAE Variables, or variables for short, are unknowns to be solved using numerical or analytical methods. A variable stores values, equation values, and addresses in the DAE array. The base class for variables is *BaseVar*. In this subsection, *BaseVar* is used to represent any subclass of *VarBase* list in the table below.

<i>BaseVar</i> ([name, tex_name, info, unit, v_str, ...])	Base variable class.
<i>ExtVar</i> (model, src[, indexer, allow_none, ...])	Externally defined algebraic variable
<i>State</i> ([name, tex_name, info, unit, v_str, ...])	Differential variable class, an alias of the <i>BaseVar</i> .
<i>Algeb</i> ([name, tex_name, info, unit, v_str, ...])	Algebraic variable class, an alias of the <i>BaseVar</i> .
<i>ExtState</i> (model, src[, indexer, allow_none, ...])	External state variable type.
<i>ExtAlgeb</i> (model, src[, indexer, allow_none, ...])	External algebraic variable type.
<i>AliasState</i> (var, **kwargs)	Alias state variable.
<i>AliasAlgeb</i> (var, **kwargs)	Alias algebraic variable.

### 4.6.1 andes.core.var.BaseVar

```
class andes.core.var.BaseVar(name: Optional[str] = None, tex_name: Optional[str] = None, info:
    Optional[str] = None, unit: Optional[str] = None, v_str:
    Optional[Union[str, float]] = None, v_iter: Optional[str] = None,
    e_str: Optional[str] = None, discrete:
    Optional[andes.core.discrete.Discrete] = None, v_setter:
    Optional[bool] = False, e_setter: Optional[bool] = False,
    v_str_add: Optional[bool] = False, addressable: Optional[bool] =
    True, export: Optional[bool] = True, diag_eps: Optional[float] =
    0.0, deps: Optional[List] = None)
```

Base variable class.

Derived classes *State* and *Algeb* should be used to build model variables.

### Parameters

- name** [str, optional] Variable name
- info** [str, optional] Descriptive information
- unit** [str, optional] Unit
- tex\_name** [str] LaTeX-formatted variable name. If is None, use *name* instead.
- discrete** [Discrete] Discrete component on which thi variable depends on. ANDES will call *check\_var()* of the discrete component before initializing this variable.

### Attributes

- a** [array-like] variable address
- v** [array-like] local-storage of the variable value
- e** [array-like] local-storage of the corresponding equation value
- e\_str** [str] the string/symbolic representation of the equation
- v\_str** [str] explicit initialization equation
- v\_str\_add** [bool] True if the value of *v\_str* will be added to the variable. Useful when other models access this variable and set part of the initial value
- v\_iter** [str] implicit iterative equation in the form of  $0 = v\_iter$

**\_\_init\_\_** (*name*: *Optional*[str] = None, *tex\_name*: *Optional*[str] = None, *info*: *Optional*[str] = None, *unit*: *Optional*[str] = None, *v\_str*: *Optional*[Union[str, float]] = None, *v\_iter*: *Optional*[str] = None, *e\_str*: *Optional*[str] = None, *discrete*: *Optional*[andes.core.discrete.Discrete] = None, *v\_setter*: *Optional*[bool] = False, *e\_setter*: *Optional*[bool] = False, *v\_str\_add*: *Optional*[bool] = False, *addressable*: *Optional*[bool] = True, *export*: *Optional*[bool] = True, *diag\_eps*: *Optional*[float] = 0.0, *deps*: *Optional*[List] = None)

### Methods

<i>get_names()</i>	
<i>reset()</i>	Reset the internal numpy arrays and flags.
<i>set_address</i> (addr[, contiguous])	Set the address of internal variables.
<i>set_arrays</i> (dae[, inplace, alloc])	Set the equation and values arrays.

**BaseVar.get\_names**

`BaseVar.get_names()`

**BaseVar.reset**

`BaseVar.reset()`

Reset the internal numpy arrays and flags.

**BaseVar.set\_address**

`BaseVar.set_address(addr: numpy.ndarray, contiguous=False)`

Set the address of internal variables.

**Parameters**

**addr** [`np.ndarray`] The assigned address for this variable

**contiguous** [`bool`, optional] If the addresses are contiguous

**BaseVar.set\_arrays**

`BaseVar.set_arrays(dae, inplace=True, alloc=True)`

Set the equation and values arrays.

**Parameters**

**dae** [`DAE`] Reference to `System.dae`

**Attributes**

---

*class\_name*

---

**BaseVar.class\_name**

**property** `BaseVar.class_name`

### 4.6.2 andes.core.var.ExtVar

```
class andes.core.var.ExtVar(model: str, src: str, indexer: Optional[Union[List, numpy.ndarray,
andes.core.param.BaseParam, andes.core.service.BaseService]] =
None, allow_none: Optional[bool] = False, name: Optional[str] =
None, tex_name: Optional[str] = None, ename: Optional[str] =
None, tex_ename: Optional[str] = None, info: Optional[str] = None,
unit: Optional[str] = None, v_str: Optional[Union[str, float]] =
None, v_iter: Optional[str] = None, e_str: Optional[str] = None,
v_setter: Optional[bool] = False, e_setter: Optional[bool] = False,
addressable: Optional[bool] = True, export: Optional[bool] = True,
diag_eps: Optional[float] = 0.0)
```

Externally defined algebraic variable

This class is used to retrieve the addresses of externally- defined variable. The *e* value of the *ExtVar* will be added to the corresponding address in the DAE equation.

#### Parameters

**model** [str] Name of the source model

**src** [str] Source variable name

**indexer** [BaseParam, BaseService] A parameter of the hosting model, used as indices into the source model and variable. If is None, the source variable address will be fully copied.

**allow\_none** [bool] True to allow None in indexer

#### Attributes

**parent\_model** [Model] The parent model providing the original parameter.

**uid** [array-like] An array containing the absolute indices into the parent\_instance values.

**e\_code** [str] Equation code string; copied from the parent instance.

**v\_code** [str] Variable code string; copied from the parent instance.

```
__init__(model: str, src: str, indexer: Optional[Union[List, numpy.ndarray,
andes.core.param.BaseParam, andes.core.service.BaseService]] = None, allow_none:
Optional[bool] = False, name: Optional[str] = None, tex_name: Optional[str] = None,
ename: Optional[str] = None, tex_ename: Optional[str] = None, info: Optional[str] =
None, unit: Optional[str] = None, v_str: Optional[Union[str, float]] = None, v_iter:
Optional[str] = None, e_str: Optional[str] = None, v_setter: Optional[bool] = False,
e_setter: Optional[bool] = False, addressable: Optional[bool] = True, export:
Optional[bool] = True, diag_eps: Optional[float] = 0.0)
```

## Methods

---

<code>get_names()</code>	
<code>link_external(ext_model)</code>	Update variable addresses provided by external models
<code>reset()</code>	Reset the internal numpy arrays and flags.
<code>set_address(addr[, contiguous])</code>	Assigns address for equation RHS.
<code>set_arrays(dae[, inplace, alloc])</code>	Access <code>dae.h</code> or <code>dae.i</code> for the RHS of external variables when <code>e_str</code> exists..

---

### ExtVar.get\_names

`ExtVar.get_names()`

### ExtVar.link\_external

`ExtVar.link_external(ext_model)`

Update variable addresses provided by external models

This method sets attributes including *parent\_model*, *parent\_instance*, *uid*, *a*, *n*, *e\_code* and *v\_code*. It initializes the *e* and *v* to zero.

#### Parameters

**ext\_model** [Model] Instance of the parent model

#### Returns

None

**Warning:** *link\_external* does not check if the *ExtVar* type is the same as the original variable to reduce performance overhead. It will be a silent error (a dimension too small error from *dae.build\_pattern*) if a model uses *ExtAlgeb* to access a *State*, or vice versa.

### ExtVar.reset

`ExtVar.reset()`

Reset the internal numpy arrays and flags.

**ExtVar.set\_address**

`ExtVar.set_address(addr, contiguous=False)`

Assigns address for equation RHS.

**ExtVar.set\_arrays**

`ExtVar.set_arrays(dae, inplace=True, alloc=True)`

Access `dae.h` or `dae.i` for the RHS of external variables when `e_str` exists..

**Attributes**

---

*class\_name*

---

**ExtVar.class\_name**

property `ExtVar.class_name`

**4.6.3 andes.core.var.State**

```
class andes.core.var.State(name: Optional[str] = None, tex_name: Optional[str] = None, info:
    Optional[str] = None, unit: Optional[str] = None, v_str:
    Optional[Union[str, float]] = None, v_iter: Optional[str] = None,
    e_str: Optional[str] = None, discrete:
    Optional[andes.core.discrete.Discrete] = None, t_const:
    Optional[Union[andes.core.param.BaseParam,
    andes.core.common.DummyValue, andes.core.service.BaseService]] =
    None, check_init: Optional[bool] = True, v_setter: Optional[bool] =
    False, e_setter: Optional[bool] = False, addressable: Optional[bool] =
    True, export: Optional[bool] = True, diag_eps: Optional[float] =
    0.0, deps: Optional[List] = None)
```

Differential variable class, an alias of the *BaseVar*.

**Parameters**

**t\_const** [*BaseParam*, *DummyValue*] Left-hand time constant for the differential equation. Time constants will not be evaluated as part of the differential equation. They will be collected to array *dae.Tf* to multiply to the right-hand side *dae.f*.

**check\_init** [*bool*] True to check if the equation right-hand-side is zero initially. Disabling the checking can be used for integrators when the initial input may not be zero.

**Attributes**

**e\_code** [str] Equation code string, equals string literal **f**

**v\_code** [str] Variable code string, equals string literal **x**

**\_\_init\_\_**(name: *Optional[str]* = None, tex\_name: *Optional[str]* = None, info: *Optional[str]* = None, unit: *Optional[str]* = None, v\_str: *Optional[Union[str, float]]* = None, v\_iter: *Optional[str]* = None, e\_str: *Optional[str]* = None, discrete: *Optional[andes.core.discrete.Discrete]* = None, t\_const: *Optional[Union[andes.core.param.BaseParam, andes.core.common.DummyValue, andes.core.service.BaseService]]* = None, check\_init: *Optional[bool]* = True, v\_setter: *Optional[bool]* = False, e\_setter: *Optional[bool]* = False, addressable: *Optional[bool]* = True, export: *Optional[bool]* = True, diag\_eps: *Optional[float]* = 0.0, deps: *Optional[List]* = None)

## Methods

---

*get\_names()*

---

<i>reset()</i>	Reset the internal numpy arrays and flags.
----------------	--

---

<i>set_address</i> (addr[, contiguous])	Set the address of internal variables.
---	--

---

<i>set_arrays</i> (dae[, inplace, alloc])	Set the equation and values arrays.
---	-------------------------------------

---

## State.get\_names

State.get\_names()

## State.reset

State.reset()

Reset the internal numpy arrays and flags.

## State.set\_address

State.set\_address(addr: *numpy.ndarray*, contiguous=False)

Set the address of internal variables.

### Parameters

**addr** [np.ndarray] The assigned address for this variable

**contiguous** [bool, optional] If the addresses are contiguous

**State.set\_arrays**

`State.set_arrays(dae, inplace=True, alloc=True)`

Set the equation and values arrays.

**Parameters**

**dae** [DAE] Reference to System.dae

**Attributes**

---

*class\_name*

---

*e\_code*

---

*v\_code*

---

**State.class\_name**

**property** `State.class_name`

**State.e\_code**

`State.e_code = 'f'`

**State.v\_code**

`State.v_code = 'x'`

**4.6.4 andes.core.var.Algeb**

```
class andes.core.var.Algeb(name: Optional[str] = None, tex_name: Optional[str] = None, info:
    Optional[str] = None, unit: Optional[str] = None, v_str:
    Optional[Union[str, float]] = None, v_iter: Optional[str] = None,
    e_str: Optional[str] = None, discrete:
    Optional[andes.core.discrete.Discrete] = None, v_setter:
    Optional[bool] = False, e_setter: Optional[bool] = False, v_str_add:
    Optional[bool] = False, addressable: Optional[bool] = True, export:
    Optional[bool] = True, diag_eps: Optional[float] = 0.0, deps:
    Optional[List] = None)
```

Algebraic variable class, an alias of the *BaseVar*.

**Attributes**

**e\_code** [str] Equation code string, equals string literal g

**v\_code** [str] Variable code string, equals string literal y

**\_\_init\_\_**(name: *Optional[str]* = None, tex\_name: *Optional[str]* = None, info: *Optional[str]* = None, unit: *Optional[str]* = None, v\_str: *Optional[Union[str, float]]* = None, v\_iter: *Optional[str]* = None, e\_str: *Optional[str]* = None, discrete: *Optional[andes.core.discrete.Discrete]* = None, v\_setter: *Optional[bool]* = False, e\_setter: *Optional[bool]* = False, v\_str\_add: *Optional[bool]* = False, addressable: *Optional[bool]* = True, export: *Optional[bool]* = True, diag\_eps: *Optional[float]* = 0.0, deps: *Optional[List]* = None)

## Methods

---

*get\_names()*

---

<i>reset()</i>	Reset the internal numpy arrays and flags.
----------------	--

<i>set_address</i> (addr[, contiguous])	Set the address of internal variables.
---	--

<i>set_arrays</i> (dae[, inplace, alloc])	Set the equation and values arrays.
---	-------------------------------------

---

## Algeb.get\_names

Algeb.get\_names()

## Algeb.reset

Algeb.reset()

Reset the internal numpy arrays and flags.

## Algeb.set\_address

Algeb.set\_address(addr: *numpy.ndarray*, contiguous=False)

Set the address of internal variables.

### Parameters

**addr** [np.ndarray] The assigned address for this variable

**contiguous** [bool, optional] If the addresses are contiguous

**Algeb.set\_arrays**

`Algeb.set_arrays(dae, inplace=True, alloc=True)`

Set the equation and values arrays.

**Parameters**

**dae** [DAE] Reference to System.dae

**Attributes**

---

*class\_name*

---

*e\_code*

---

*v\_code*

---

**Algeb.class\_name**

**property** `Algeb.class_name`

**Algeb.e\_code**

`Algeb.e_code = 'g'`

**Algeb.v\_code**

`Algeb.v_code = 'y'`

**4.6.5 andes.core.var.ExtState**

```
class andes.core.var.ExtState(model: str, src: str, indexer: Optional[Union[List, numpy.ndarray,
andes.core.param.BaseParam, andes.core.service.BaseService]] =
None, allow_none: Optional[bool] = False, name: Optional[str] =
None, tex_name: Optional[str] = None, ename: Optional[str] =
None, tex_ename: Optional[str] = None, info: Optional[str] =
None, unit: Optional[str] = None, v_str: Optional[Union[str,
float]] = None, v_iter: Optional[str] = None, e_str: Optional[str]
= None, v_setter: Optional[bool] = False, e_setter: Optional[bool]
= False, addressable: Optional[bool] = True, export:
Optional[bool] = True, diag_eps: Optional[float] = 0.0)
```

External state variable type.

**Warning:** `ExtState` is not allowed to set `t_const`, as it will conflict with the source `State` variable. In fact, one should not set `e_str` for `ExtState`.

```
__init__(model: str, src: str, indexer: Optional[Union[List, numpy.ndarray,
andes.core.param.BaseParam, andes.core.service.BaseService]]) = None, allow_none:
Optional[bool] = False, name: Optional[str] = None, tex_name: Optional[str] = None,
ename: Optional[str] = None, tex_ename: Optional[str] = None, info: Optional[str] =
None, unit: Optional[str] = None, v_str: Optional[Union[str, float]] = None, v_iter:
Optional[str] = None, e_str: Optional[str] = None, v_setter: Optional[bool] = False,
e_setter: Optional[bool] = False, addressable: Optional[bool] = True, export:
Optional[bool] = True, diag_eps: Optional[float] = 0.0)
```

## Methods

<code>get_names()</code>	
<code>link_external(ext_model)</code>	Update variable addresses provided by external models
<code>reset()</code>	Reset the internal numpy arrays and flags.
<code>set_address(addr[, contiguous])</code>	Assigns address for equation RHS.
<code>set_arrays(dae[, inplace, alloc])</code>	Access <code>dae.h</code> or <code>dae.i</code> for the RHS of external variables when <code>e_str</code> exists..

## `ExtState.get_names`

`ExtState.get_names()`

## `ExtState.link_external`

`ExtState.link_external(ext_model)`

Update variable addresses provided by external models

This method sets attributes including `parent_model`, `parent_instance`, `uid`, `a`, `n`, `e_code` and `v_code`. It initializes the `e` and `v` to zero.

### Parameters

**ext\_model** [Model] Instance of the parent model

### Returns

None

**Warning:** *link\_external* does not check if the ExtVar type is the same as the original variable to reduce performance overhead. It will be a silent error (a dimension too small error from *dae.build\_pattern*) if a model uses *ExtAlgeb* to access a *State*, or vice versa.

### ExtState.reset

`ExtState.reset()`

Reset the internal numpy arrays and flags.

### ExtState.set\_address

`ExtState.set_address(addr, contiguous=False)`

Assigns address for equation RHS.

### ExtState.set\_arrays

`ExtState.set_arrays(dae, inplace=True, alloc=True)`

Access `dae.h` or `dae.i` for the RHS of external variables when `e_str` exists..

### Attributes

---

*class\_name*

---

*e\_code*

---

*t\_const*

---

*v\_code*

---

### ExtState.class\_name

**property** `ExtState.class_name`

**ExtState.e\_code**

```
ExtState.e_code = 'f'
```

**ExtState.t\_const**

```
ExtState.t_const = None
```

**ExtState.v\_code**

```
ExtState.v_code = 'x'
```

**4.6.6 andes.core.var.ExtAlgeb**

```
class andes.core.var.ExtAlgeb(model: str, src: str, indexer: Optional[Union[List, numpy.ndarray,
    andes.core.param.BaseParam, andes.core.service.BaseService]] =
    None, allow_none: Optional[bool] = False, name: Optional[str] =
    None, tex_name: Optional[str] = None, ename: Optional[str] =
    None, tex_ename: Optional[str] = None, info: Optional[str] =
    None, unit: Optional[str] = None, v_str: Optional[Union[str,
    float]] = None, v_iter: Optional[str] = None, e_str: Optional[str]
    = None, v_setter: Optional[bool] = False, e_setter: Optional[bool]
    = False, addressable: Optional[bool] = True, export:
    Optional[bool] = True, diag_eps: Optional[float] = 0.0)
```

External algebraic variable type.

```
__init__(model: str, src: str, indexer: Optional[Union[List, numpy.ndarray,
    andes.core.param.BaseParam, andes.core.service.BaseService]] = None, allow_none:
    Optional[bool] = False, name: Optional[str] = None, tex_name: Optional[str] = None,
    ename: Optional[str] = None, tex_ename: Optional[str] = None, info: Optional[str] =
    None, unit: Optional[str] = None, v_str: Optional[Union[str, float]] = None, v_iter:
    Optional[str] = None, e_str: Optional[str] = None, v_setter: Optional[bool] = False,
    e_setter: Optional[bool] = False, addressable: Optional[bool] = True, export:
    Optional[bool] = True, diag_eps: Optional[float] = 0.0)
```

**Methods**

---

<code>get_names()</code>	
<code>link_external(ext_model)</code>	Update variable addresses provided by external models
<code>reset()</code>	Reset the internal numpy arrays and flags.
<code>set_address(addr[, contiguous])</code>	Assigns address for equation RHS.

---

continues on next page

Table 34 – continued from previous page

<code>set_arrays(dae[, inplace, alloc])</code>	Access <code>dae.h</code> or <code>dae.i</code> for the RHS of external variables when <code>e_str</code> exists..
--	--

**ExtAlgeb.get\_names**

`ExtAlgeb.get_names()`

**ExtAlgeb.link\_external**

`ExtAlgeb.link_external(ext_model)`

Update variable addresses provided by external models

This method sets attributes including *parent\_model*, *parent\_instance*, *uid*, *a*, *n*, *e\_code* and *v\_code*. It initializes the *e* and *v* to zero.

**Parameters**

**ext\_model** [Model] Instance of the parent model

**Returns**

None

**Warning:** *link\_external* does not check if the *ExtVar* type is the same as the original variable to reduce performance overhead. It will be a silent error (a dimension too small error from *dae.build\_pattern*) if a model uses *ExtAlgeb* to access a *State*, or vice versa.

**ExtAlgeb.reset**

`ExtAlgeb.reset()`

Reset the internal numpy arrays and flags.

**ExtAlgeb.set\_address**

`ExtAlgeb.set_address(addr, contiguous=False)`

Assigns address for equation RHS.

**ExtAlgeb.set\_arrays**

`ExtAlgeb.set_arrays(dae, inplace=True, alloc=True)`

Access `dae.h` or `dae.i` for the RHS of external variables when `e_str` exists..

**Attributes**

---

*class\_name*

---

*e\_code*

---

*v\_code*

---

**ExtAlgeb.class\_name**

**property** `ExtAlgeb.class_name`

**ExtAlgeb.e\_code**

`ExtAlgeb.e_code = 'g'`

**ExtAlgeb.v\_code**

`ExtAlgeb.v_code = 'y'`

**4.6.7 andes.core.var.AliasState**

**class** `andes.core.var.AliasState(var, **kwargs)`

Alias state variable.

Refer to the docs of `AliasAlgeb`.

**\_\_init\_\_**(var, \*\*kwargs)

## Methods

---

<code>get_names()</code>	
<code>link_external(ext_model)</code>	Update variable addresses provided by external models
<code>reset()</code>	Reset the internal numpy arrays and flags.
<code>set_address(addr[, contiguous])</code>	Assigns address for equation RHS.
<code>set_arrays(dae[, inplace, alloc])</code>	Access <code>dae.h</code> or <code>dae.i</code> for the RHS of external variables when <code>e_str</code> exists..

---

### AliasState.get\_names

`AliasState.get_names()`

### AliasState.link\_external

`AliasState.link_external(ext_model)`

Update variable addresses provided by external models

This method sets attributes including *parent\_model*, *parent\_instance*, *uid*, *a*, *n*, *e\_code* and *v\_code*. It initializes the *e* and *v* to zero.

#### Parameters

**ext\_model** [Model] Instance of the parent model

#### Returns

None

**Warning:** *link\_external* does not check if the ExtVar type is the same as the original variable to reduce performance overhead. It will be a silent error (a dimension too small error from *dae.build\_pattern*) if a model uses *ExtAlgeb* to access a *State*, or vice versa.

### AliasState.reset

`AliasState.reset()`

Reset the internal numpy arrays and flags.

**AliasState.set\_address**

`AliasState.set_address(addr, contiguous=False)`

Assigns address for equation RHS.

**AliasState.set\_arrays**

`AliasState.set_arrays(dae, inplace=True, alloc=True)`

Access `dae.h` or `dae.i` for the RHS of external variables when `e_str` exists..

**Attributes**

---

*class\_name*

---

*e\_code*

---

*t\_const*

---

*v\_code*

---

**AliasState.class\_name**

**property** `AliasState.class_name`

**AliasState.e\_code**

`AliasState.e_code = 'f'`

**AliasState.t\_const**

`AliasState.t_const = None`

**AliasState.v\_code**

`AliasState.v_code = 'x'`

## 4.6.8 andes.core.var.AliasAlgeb

**class** andes.core.var.AliasAlgeb(*var*, **\*\*kwargs**)

Alias algebraic variable. Essentially ExtAlgeb that links to a model's own variable.

AliasAlgeb is useful when the final output of a model is from a block, but the model must provide the final output in a pre-defined name. Using AliasAlgeb, A model can avoid adding an additional variable with a dummy equations.

Like ExtVar, labels of AliasAlgeb will not be saved in the final output. When plotting from file, one need to look up the original variable name.

**\_\_init\_\_**(*var*, **\*\*kwargs**)

### Methods

---

*get\_names*()

---

<i>link_external</i> ( <i>ext_model</i> )	Update variable addresses provided by external models
---	---

---

<i>reset</i> ()	Reset the internal numpy arrays and flags.
-----------------	--

---

<i>set_address</i> ( <i>addr</i> [, <i>contiguous</i> ])	Assigns address for equation RHS.
--	-----------------------------------

---

<i>set_arrays</i> ( <i>dae</i> [, <i>inplace</i> , <i>alloc</i> ])	Access <i>dae.h</i> or <i>dae.i</i> for the RHS of external variables when <i>e_str</i> exists..
--	--

---

### AliasAlgeb.get\_names

AliasAlgeb.get\_names()

### AliasAlgeb.link\_external

AliasAlgeb.link\_external(*ext\_model*)

Update variable addresses provided by external models

This method sets attributes including *parent\_model*, *parent\_instance*, *uid*, *a*, *n*, *e\_code* and *v\_code*. It initializes the *e* and *v* to zero.

#### Parameters

**ext\_model** [Model] Instance of the parent model

#### Returns

None

**Warning:** *link\_external* does not check if the ExtVar type is the same as the original variable to reduce performance overhead. It will be a silent error (a dimension too small error from *dae.build\_pattern*) if a model uses *ExtAlgeb* to access a *State*, or vice versa.

### AliasAlgeb.reset

AliasAlgeb.**reset**()

Reset the internal numpy arrays and flags.

### AliasAlgeb.set\_address

AliasAlgeb.**set\_address**(*addr*, *contiguous=False*)

Assigns address for equation RHS.

### AliasAlgeb.set\_arrays

AliasAlgeb.**set\_arrays**(*dae*, *inplace=True*, *alloc=True*)

Access *dae.h* or *dae.i* for the RHS of external variables when *e\_str* exists..

### Attributes

---

*class\_name*

---

*e\_code*

---

*v\_code*

---

### AliasAlgeb.class\_name

**property** AliasAlgeb.**class\_name**

### AliasAlgeb.e\_code

```
AliasAlgeb.e_code = 'g'
```

### AliasAlgeb.v\_code

```
AliasAlgeb.v_code = 'y'
```

Note that equations associated with state variables are in the form of  $M\dot{x} = f(x, y)$ , where  $x$  are the differential variables,  $y$  are the algebraic variables, and  $M$  is the mass matrix, and  $f$  are the right-hand side of differential equations. Equations associated with algebraic variables take the form of  $0 = g$ , where  $g$  are the equation right-hand side

*BaseVar* has two types: the differential variable type *State* and the algebraic variable type *Algeb*. State variables are described by differential equations, whereas algebraic variables are described by algebraic equations. State variables can only change continuously, while algebraic variables can be discontinuous.

Based on the model the variable is defined, variables can be internal or external. Most variables are internal and only appear in equations in the same model. Some models have "public" variables that can be accessed by other models. For example, a *Bus* defines  $v$  for the voltage magnitude. Each device attached to a particular bus needs to access the value and impose the reactive power injection. It can be done with *ExtAlgeb* or *ExtState*, which links with an existing variable from a model or a group.

## 4.6.9 Variable, Equation and Address

Subclasses of *BaseVar* are value providers and equation providers. Each *BaseVar* has member attributes  $v$  and  $e$  for variable values and equation values, respectively. The initial value of  $v$  is set by the initialization routine, and the initial value of  $e$  is set to zero. In the process of power flow calculation or time domain simulation,  $v$  is not directly modifiable by models but rather updated after solving non-linear equations.  $e$  is updated by the models and summed up before solving equations.

Each *BaseVar* also stores addresses of this variable, for all devices, in its member attribute  $a$ . The addresses are *0-based* indices into the numerical DAE array,  $f$  or  $g$ , based on the variable type.

For example, *Bus* has `self.a = Algeb()` as the voltage phase angle variable. For a 5-bus system, `Bus.a.a` stores the addresses of the  $a$  variable for all the five *Bus* devices. Conventionally, `Bus.a.a` will be assigned `np.array([0, 1, 2, 3, 4])`.

## 4.6.10 Value and Equation Strings

The most important feature of the symbolic framework is allowing to define equations using strings. There are three types of strings for a variable, stored in the following member attributes, respectively:

- $v\_str$ : equation string for **explicit** initialization in the form of  $v = v\_str(x, y)$ .
- $v\_iter$ : equation string for **implicit** initialization in the form of  $v\_iter(x, y) = 0$
- $e\_str$ : equation string for (full or part of) the differential or algebraic equation.

The difference between `v_str` and `v_iter` should be clearly noted. `v_str` evaluates directly into the initial value, while all `v_iter` equations are solved numerically using the Newton-Krylov iterative method.

#### 4.6.11 Values Between DAE and Models

ANDES adopts a decentralized architecture which provides each model a copy of variable values before equation evaluation. This architecture allows to parallelize the equation evaluation (in theory, or in practice if one works round the Python GIL). However, this architecture requires a coherent protocol for updating the DAE arrays and the `BaseVar` arrays. More specifically, how the variable and equations values from model `VarBase` should be summed up or forcefully set at the DAE arrays needs to be defined.

The protocol is relevant when a model defines subclasses of `BaseVar` that are supposed to be "public". Other models share this variable with `ExtAlgeb` or `ExtState`.

By default, all `v` and `e` at the same address are summed up. This is the most common case, such as a Bus connected by multiple devices: power injections from devices should be summed up.

In addition, `BaseVar` provides two flags, `v_setter` and `e_setter`, for cases when one `VarBase` needs to overwrite the variable or equation values.

#### 4.6.12 Flags for Value Overwriting

`BaseVar` have special flags for handling value initialization and equation values. This is only relevant for public or external variables. The `v_setter` is used to indicate whether a particular `BaseVar` instance sets the initial value. The `e_setter` flag indicates whether the equation associated with a `BaseVar` sets the equation value.

The `v_setter` flag is checked when collecting data from models to the numerical DAE array. If `v_setter` is `False`, variable values of the same address will be added. If one of the variable or external variable has `v_setter` is `True`, it will, at the end, set the values in the DAE array to its value. Only one `BaseVar` of the same address is allowed to have `v_setter == True`.

#### 4.6.13 A `v_setter` Example

A Bus is allowed to default the initial voltage magnitude to 1 and the voltage phase angle to 0. If a PV device is connected to a Bus device, the PV should be allowed to override the voltage initial value with the voltage set point.

In `Bus.__init__()`, one has

```
self.v = Algeb(v_str='1')
```

In `PV.__init__`, one can use

```
self.v0 = Param()
self.bus = IdxParam(model='Bus')

self.v = ExtAlgeb(src='v',
```

(continues on next page)

(continued from previous page)

```

model='Bus',
indexer=self.bus,
v_str='v0',
v_setter=True)

```

where an *ExtAlgeb* is defined to access *Bus.v* using indexer *self.bus*. The *v\_str* line sets the initial value to *v0*. In the variable initialization phase for *PV*, *PV.v.v* is set to *v0*.

During the value collection into *DAE.y* by the *System* class, *PV.v*, as a final *v\_setter*, will overwrite the voltage magnitude for Bus devices with the indices provided in *PV.bus*.

## 4.7 Services

Services are helper variables outside the DAE variable list. Services are most often used for storing intermediate constants but can be used for special operations to work around restrictions in the symbolic framework. Services are value providers, meaning each service has an attribute *v* for storing service values. The base class of services is `:py:mod`BaseService``, and the supported services are listed as follows.

<code>BaseService([name, tex_name, info, vtype])</code>	Base class for Service.
<code>OperationService([name, tex_name, info])</code>	Base class for a type of Service which performs specific operations.

### 4.7.1 andes.core.service.BaseService

```

class andes.core.service.BaseService(name: Optional[str] = None, tex_name: Optional[str] =
None, info: Optional[str] = None, vtype: Optional[Type]
= None)

```

Base class for Service.

Service is a v-provider type for holding internal and temporary values. Subclasses need to implement *v* as a member attribute or using a property decorator.

#### Parameters

**name** [str] Instance name

#### Attributes

**owner** [Model] The hosting/owner model instance

```

__init__(name: Optional[str] = None, tex_name: Optional[str] = None, info: Optional[str] =
None, vtype: Optional[Type] = None)

```

## Methods

<code>assign_memory(n)</code>	Assign memory for <code>self.v</code> and set the array to zero.
<code>get_names()</code>	Return <i>name</i> in a list

### BaseService.assign\_memory

**BaseService.assign\_memory(*n*)**  
Assign memory for `self.v` and set the array to zero.

#### Parameters

**n** [int] Number of elements of the value array. Provided by caller (`Model.list2array`).

### BaseService.get\_names

**BaseService.get\_names()**  
Return *name* in a list

#### Returns

**list** A list only containing the name of the service variable

## Attributes

<code>class_name</code>	Return the class name
<code>n</code>	Return the count of values in <code>self.v</code> .

### BaseService.class\_name

**property BaseService.class\_name**  
Return the class name

### BaseService.n

**property BaseService.n**  
Return the count of values in `self.v`.  
Needs to be overloaded if `v` of subclasses is not a 1-dimensional array.

#### Returns

**int** The count of elements in this variable

### 4.7.2 andes.core.service.OperationService

**class** andes.core.service.OperationService(*name=None, tex\_name=None, info=None*)

Base class for a type of Service which performs specific operations. OperationService may not use the *assign\_memory* from *BaseService*, because it can have a different size.

This class cannot be used by itself.

**See also:**

**NumReduce** Service for Reducing linearly stored 2-D services into 1-D

**NumRepeat** Service for repeating 1-D NumParam/ v-array following a sub-pattern

**IdxRepeat** Service for repeating 1-D IdxParam/ v-list following a sub-pattern

**\_\_init\_\_**(*name=None, tex\_name=None, info=None*)

#### Methods

<i>assign_memory</i> ( <i>n</i> )	Assign memory for <i>self.v</i> and set the array to zero.
<i>get_names</i> ()	Return <i>name</i> in a list

#### OperationService.assign\_memory

OperationService.**assign\_memory**(*n*)

Assign memory for *self.v* and set the array to zero.

##### Parameters

**n** [int] Number of elements of the value array. Provided by caller (Model.list2array).

#### OperationService.get\_names

OperationService.**get\_names**()

Return *name* in a list

##### Returns

**list** A list only containing the name of the service variable

## Attributes

<i>class_name</i>	Return the class name
<i>n</i>	Return the count of values in <code>self.v</code> .
<i>v</i>	Return values stored in <i>self.v</i> .

### OperationService.class\_name

**property** OperationService.class\_name  
Return the class name

### OperationService.n

**property** OperationService.n  
Return the count of values in `self.v`.  
  
Needs to be overloaded if `v` of subclasses is not a 1-dimensional array.

#### Returns

**int** The count of elements in this variable

### OperationService.v

**property** OperationService.v  
Return values stored in *self.v*. May be overloaded by subclasses.

Class	Description
ConstService	Internal service for constant values.
VarService	Variable service updated at each iteration before equations.
ExtService	External service for retrieving values from value providers.
PostInitService	Constant service evaluated after TDS initialization
NumReduce	The service type for reducing linear 2-D arrays into 1-D arrays
NumRepeat	The service type for repeating a 1-D array to linear 2-D arrays
IdxRepeat	The service type for repeating a 1-D list to linear 2-D list
EventFlag	Service type for flagging changes in inputs as an event
VarHold	Hold input value when a hold signal is active
ExtendedEvent	Extend an event signal for a given period of time
DataSelect	Select optional str data if provided or use the fallback
NumSelect	Select optional numerical data if provided
DeviceFinder	Finds or creates devices linked to the given devices
BackRef	Collects idx-es for the backward references
RefFlatten	Converts BackRef list of lists into a 1-D list
InitChecker	Checks initial values against typical values
FlagValue	Flags values that equals the given value
Replace	Replace values that returns True for the given lambda func

### 4.7.3 Internal Constants

The most commonly used service is *ConstService*. It is used to store an array of constants, whose value is evaluated from a provided symbolic string. They are only evaluated once in the model initialization phase, ahead of variable initialization. *ConstService* comes handy when one wants to calculate intermediate constants from parameters.

For example, a turbine governor has a *NumParam* *R* for the droop. *ConstService* allows to calculate the inverse of the droop, the gain, and use it in equations. The snippet from a turbine governor's `__init__()` may look like

```
self.R = NumParam()
self.G = ConstService(v_str='u/R')
```

where *u* is the online status parameter. The model can thus use *G* in subsequent variable or equation strings.

```
class andes.core.service.ConstService(v_str: Optional[str] = None, v_numeric:
    Optional[Callable] = None, vtype: Optional[type] =
    None, name: Optional[str] = None, tex_name=None,
    info=None)
```

A type of Service that stays constant once initialized.

ConstService are usually constants calculated from parameters. They are only evaluated once in the initialization phase before variables are initialized. Therefore, uninitialized variables must not be used in `v_str`.

#### Parameters

**name** [str] Name of the ConstService

**v\_str** [str] An equation string to calculate the variable value.

**v\_numeric** [Callable, optional] A callable which returns the value of the ConstService

### Attributes

**v** [array-like or a scalar] ConstService value

```
class andes.core.service.VarService(v_str: Optional[str] = None, v_numeric:
    Optional[Callable] = None, vtype: Optional[type] = None,
    name: Optional[str] = None, tex_name=None, info=None)
```

Variable service that gets updated in each step/loop as variables change.

This class is useful when one has non-differentiable algebraic equations, which make use of *abs()*, *re* and *im*. Instead of creating *Algeb*, one can put the equation in *VarService*, which will be updated before solving algebraic equations.

**Warning:** *VarService* is not solved with other algebraic equations, meaning that there is one step "delay" between the algebraic variables and *VarService*. Use an algebraic variable whenever possible.

### Examples

In ESST3A model, the voltage and current sensors ( $v_d + jv_q$ ), ( $I_d + jI_q$ ) estimate the sensed VE using equation

$$VE = |K_{PC} * (v_d + 1jv_q) + 1j(K_I + K_{PC} * X_L) * (I_d + 1jI_q)|$$

One can use *VarService* to implement this equation

```
self.VE = VarService(
    tex_name='V_E',
    info='VE',
    v_str='Abs(KPC*(vd + 1j*vq) + 1j*(KI + KPC*XL)*(Id + 1j*Iq))',
)
```

```
class andes.core.service.PostInitService(v_str: Optional[str] = None, v_numeric:
    Optional[Callable] = None, vtype: Optional[type] =
    None, name: Optional[str] = None, tex_name=None,
    info=None)
```

Constant service that gets stored once after init.

This service is useful when one need to store initialization values stored in variables.

## Examples

In ESST3A model, the  $vf$  variable is initialized followed by other variables. One can store the initial  $vf$  into  $vf0$  so that equation  $vf - vf0 = 0$  will hold.

```
self.vref0 = PostInitService(info='Initial reference voltage input',
                             tex_name='V_{ref0}',
                             v_str='vref',
                             )
```

Since all *ConstService* are evaluated before equation evaluation, without using *PostInitService*, one will need to create lots of *ConstService* to store values in the initialization path towards  $vf0$ , in order to correctly initialize  $vf$ .

## 4.7.4 External Constants

Service constants whose value is retrieved from an external model or group. Using *ExtService* is similar to using external variables. The values of *ExtService* will be retrieved once during the initialization phase before *ConstService* evaluation.

For example, a synchronous generator needs to retrieve the  $p$  and  $q$  values from static generators for initialization. *ExtService* is used for this purpose. In the `__init__()` of a synchronous generator model, one can define the following to retrieve *StaticGen.p* as  $p0$ :

```
self.p0 = ExtService(src='p',
                     model='StaticGen',
                     indexer=self.gen,
                     tex_name='P_0')
```

```
class andes.core.service.ExtService(model: str, src: str, indexer:
    Union[andes.core.param.BaseParam,
    andes.core.service.BaseService], attr: str = 'v',
    allow_none: bool = False, default=0, name: Optional[str]
    = None, tex_name: Optional[str] = None, vtype=None,
    info: Optional[str] = None)
```

Service constants whose value is from an external model or group.

### Parameters

**src** [str] Variable or parameter name in the source model or group

**model** [str] A model name or a group name

**indexer** [IdxParam or BaseParam] An "Indexer" instance whose `v` field contains the `idx` of devices in the model or group.

## Examples

A synchronous generator needs to retrieve the `p` and `q` values from static generators for initialization. `ExtService` is used for this purpose.

In a synchronous generator, one can define the following to retrieve `StaticGen.p` as `p0`:

```
class GENCLModel(Model):
    def __init__(...):
        ...
        self.p0 = ExtService(src='p',
                             model='StaticGen',
                             indexer=self.gen,
                             tex_name='P_0')
```

## 4.7.5 Shape Manipulators

This section is for advanced model developer.

All generated equations operate on 1-dimensional arrays and can use algebraic calculations only. In some cases, one model would use *BackRef* to retrieve 2-dimensional indices and will use such indices to retrieve variable addresses. The retrieved addresses usually has a different length of the referencing model and cannot be used directly for calculation. Shape manipulator services can be used in such case.

*NumReduce* is a helper Service type which reduces a linearly stored 2-D ExtParam into 1-D Service. *NumRepeat* is a helper Service type which repeats a 1-D value into linearly stored 2-D value based on the shape from a *BackRef*.

**class andes.core.service.BackRef(\*\*kwargs)**

A special type of reference collector.

*BackRef* is used for collecting device indices of other models referencing the parent model of the *BackRef*. The *v`field* will be a list of lists, each containing the *idx* of other models referencing each device of the parent model.

*BackRef* can be passed as indexer for params and vars, or shape for *NumReduce* and *NumRepeat*. See examples for illustration.

**See also:**

**andes.core.service.NumReduce** A more complete example using *BackRef* to build the COI model

## Examples

A Bus device has an *IdxParam* of *area*, storing the *idx* of area to which the bus device belongs. In `Bus.__init__()`, one has

```
self.area = IdxParam(model='Area')
```

Suppose *Bus* has the following data

idx	area	Vn
1	1	110
2	2	220
3	1	345
4	1	500

The Area model wants to collect the indices of Bus devices which points to the corresponding Area device. In `Area.__init__`, one defines

```
self.Bus = BackRef()
```

where the member attribute name *Bus* needs to match exactly model name that *Area* wants to collect *idx* for. Similarly, one can define `self.ACTopology = BackRef()` to collect devices in the *ACTopology* group that references Area.

The collection of *idx* happens in `andes.system.System._collect_ref_param()`. It has to be noted that the specific *Area* entry must exist to collect model idx-dx referencing it. For example, if *Area* has the following data

```
idx
1
```

Then, only Bus 1, 3, and 4 will be collected into `self.Bus.v`, namely, `self.Bus.v == [ [1, 3, 4] ]`.

If *Area* has data

```
idx
1
2
```

Then, `self.Bus.v` will end up with `[ [1, 3, 4], [2] ]`.

```
class andes.core.service.NumReduce(u, ref: andes.core.service.BackRef, fun: Callable,
                                   name=None, tex_name=None, info=None, cache=True)
```

A helper Service type which reduces a linearly stored 2-D ExtParam into 1-D Service.

NumReduce works with ExtParam whose *v* field is a list of lists. A reduce function which takes an array-like and returns a scalar need to be supplied. NumReduce calls the reduce function on each of the lists and return all the scalars in an array.

### Parameters

- u** [ExtParam] Input ExtParam whose *v* contains linearly stored 2-dimensional values
- ref** [BackRef] The BackRef whose 2-dimensional shapes are used for indexing
- fun** [Callable] The callable for converting a 1-D array-like to a scalar

## Examples

Suppose one wants to calculate the mean value of the *Vn* in one Area. In the *Area* class, one defines

```
class AreaModel(...):
    def __init__(...):
        ...
        # backward reference from `Bus`
        self.Bus = BackRef()

        # collect the Vn in an 1-D array
        self.Vn = ExtParam(model='Bus',
                             src='Vn',
                             indexer=self.Bus)

        self.Vn_mean = NumReduce(u=self.Vn,
                                  fun=np.mean,
                                  ref=self.Bus)
```

Suppose we define two areas, 1 and 2, the *Bus* data looks like

idx	area	Vn
1	1	110
2	2	220
3	1	345
4	1	500

Then, *self.Bus.v* is a list of two lists [ [1, 3, 4], [2] ]. *self.Vn.v* will be retrieved and linearly stored as [110, 345, 500, 220]. Based on the shape from *self.Bus*, `numpy.mean()` will be called on [110, 345, 500] and [220] respectively. Thus, *self.Vn\_mean.v* will become [318.33, 220].

**class** `andes.core.service.NumRepeat(u, ref, **kwargs)`

A helper Service type which repeats a v-provider's value based on the shape from a BackRef

## Examples

NumRepeat was originally designed for computing the inertia-weighted average rotor speed (center of inertia speed). COI speed is computed with

$$\omega_{COI} = \frac{\sum M_i * \omega_i}{\sum M_i}$$

The numerator can be calculated with a mix of BackRef, ExtParam and ExtState. The denominator needs to be calculated with NumReduce and Service Repeat. That is, use NumReduce to calculate the sum, and use NumRepeat to repeat the summed value for each device.

In the COI class, one would have

```
class COIModel(...):
    def __init__(...):
        ...
        self.SynGen = BackRef()
        self.SynGenIdx = RefFlatten(ref=self.SynGen)
        self.M = ExtParam(model='SynGen',
                           src='M',
                           indexer=self.SynGenIdx)

        self.wgen = ExtState(model='SynGen',
                              src='omega',
                              indexer=self.SynGenIdx)

        self.Mt = NumReduce(u=self.M,
                             fun=np.sum,
                             ref=self.SynGen)

        self.Mtr = NumRepeat(u=self.Mt,
                              ref=self.SynGen)

        self.pidx = IdxRepeat(u=self.idx, ref=self.SynGen)
```

Finally, one would define the center of inertia speed as

```
self.wcoi = Algeb(v_str='1', e_str='-wcoi')

self.wcoi_sub = ExtAlgeb(model='COI',
                          src='wcoi',
                          e_str='M * wgen / Mtr',
                          v_str='M / Mtr',
                          indexer=self.pidx,
                          )
```

It is very worth noting that the implementation uses a trick to separate the average weighted sum into  $n$  sub-equations, each calculating the  $(M_i * \omega_i) / (\sum M_i)$ . Since all the variables are preserved in the sub-equation, the derivatives can be calculated correctly.

**class** andes.core.service.IdxRepeat(*u, ref, \*\*kwargs*)

Helper class to repeat IdxParam.

This class has the same functionality as `andes.core.service.NumRepeat` but only operates on `IdxParam`, `DataParam` or `NumParam`.

**class** andes.core.service.Refflatten(*ref, \*\*kwargs*)

A service type for flattening `andes.core.service.BackRef` into a 1-D list.

## Examples

This class is used when one wants to pass *BackRef* values as indexer.

`andes.models.coi.COI` collects referencing `andes.models.group.SynGen` with

```
self.SynGen = BackRef(info='SynGen idx lists', export=False)
```

After collecting *BackRefs*, `self.SynGen.v` will become a two-level list of indices, where the first level correspond to each COI and the second level correspond to generators of the COI.

Convert `self.SynGen` into 1-d as `self.SynGenIdx`, which can be passed as indexer for retrieving other parameters and variables

```
self.SynGenIdx = Refflatten(ref=self.SynGen)

self.M = ExtParam(model='SynGen', src='M',
                  indexer=self.SynGenIdx, export=False,
                  )
```

## 4.7.6 Value Manipulation

**class** andes.core.service.Replace(*old\_val, fct, new\_val, name=None, tex\_name=None, info=None, cache=True*)

Replace parameters with new values if the function returns True

**class** andes.core.service.ParamCalc(*param1, param2, func, name=None, tex\_name=None, info=None, cache=True*)

Parameter calculation service.

Useful to create parameters calculated instantly from existing ones.

### 4.7.7 Idx and References

**class** andes.core.service.**DeviceFinder**(*u, link, idx\_name, name=None, tex\_name=None, info=None*)

Service for finding indices of optionally linked devices.

If not provided, *DeviceFinder* will add devices at the beginning of *System.setup*.

#### Examples

IEEEEST stabilizer takes an optional *busf* (IdxParam) for specifying the connected BusFreq, which is needed for mode 6. To avoid reimplementing *BusFreq* within IEEEEST, one can do

```
self.busfreq = DeviceFinder(self.busf, link=self.buss, idx_name='bus')
```

where *self.busf* is the optional input, *self.buss* is the bus indices that *busf* should measure, and *idx\_name* is the name of a BusFreq parameter through which the measured bus indices are specified. For each *None* values in *self.busf*, a *BusFreq* is created to measure the corresponding bus in *self.buss*.

That is, *BusFreq[idx\_name].v = [link]*. *DeviceFinder* will find / create *BusFreq* devices so that the returned list of *BusFreq* indices are connected to *self.buss*, respectively.

**class** andes.core.service.**BackRef**(\*\**kwargs*)

A special type of reference collector.

*BackRef* is used for collecting device indices of other models referencing the parent model of the *BackRef*. The *v`field* will be a list of lists, each containing the *idx* of other models referencing each device of the parent model.

*BackRef* can be passed as indexer for params and vars, or shape for *NumReduce* and *NumRepeat*. See examples for illustration.

**See also:**

**andes.core.service.NumReduce** A more complete example using *BackRef* to build the COI model

#### Examples

A Bus device has an *IdxParam* of *area*, storing the *idx* of area to which the bus device belongs. In *Bus.\_\_init\_\_()*, one has

```
self.area = IdxParam(model='Area')
```

Suppose *Bus* has the following data

idx	area	Vn
1	1	110
2	2	220
3	1	345
4	1	500

The Area model wants to collect the indices of Bus devices which points to the corresponding Area device. In `Area.__init__`, one defines

```
self.Bus = BackRef()
```

where the member attribute name *Bus* needs to match exactly model name that *Area* wants to collect *idx* for. Similarly, one can define `self.ACTopology = BackRef()` to collect devices in the *ACTopology* group that references Area.

The collection of *idx* happens in `andes.system.System._collect_ref_param()`. It has to be noted that the specific *Area* entry must exist to collect model idx-dx referencing it. For example, if *Area* has the following data

```
idx
1
```

Then, only Bus 1, 3, and 4 will be collected into `self.Bus.v`, namely, `self.Bus.v == [ [1, 3, 4] ]`.

If *Area* has data

```
idx
1
2
```

Then, `self.Bus.v` will end up with `[ [1, 3, 4], [2] ]`.

**class** `andes.core.service.RefFlatten(ref, **kwargs)`

A service type for flattening `andes.core.service.BackRef` into a 1-D list.

## Examples

This class is used when one wants to pass *BackRef* values as indexer.

`andes.models.coi.COI` collects referencing `andes.models.group.SynGen` with

```
self.SynGen = BackRef(info='SynGen idx lists', export=False)
```

After collecting BackRefs, `self.SynGen.v` will become a two-level list of indices, where the first level correspond to each COI and the second level correspond to generators of the COI.

Convert `self.SynGen` into 1-d as `self.SynGenIdx`, which can be passed as indexer for retrieving other parameters and variables

```

self.SynGenIdx = RefFlatten(ref=self.SynGen)

self.M = ExtParam(model='SynGen', src='M',
                  indexer=self.SynGenIdx, export=False,
                  )

```

#### 4.7.8 Events

**class** andes.core.service.**EventFlag**(*u*, *vtype*: *Optional*[*type*] = *None*, *name*: *Optional*[*str*] = *None*, *tex\_name*=*None*, *info*=*None*)

Service to flag events when the input value changes. The typical input is a *v-provider* with binary values.

Implemented by providing *self.check(\*\*kwargs)* as *v\_numeric*. *EventFlag.v* stores the values of the input variable in the most recent iteration/step.

After the evaluation of *self.check()*, *self.v* will be updated.

**class** andes.core.service.**ExtendedEvent**(*u*, *t\_ext*: *Union*[*int*, *float*, andes.core.param.BaseParam, andes.core.service.BaseService] = 0.0, *trig*: *str* = 'rise', *enable*=*True*, *v\_disabled*=0, *extend\_only*=*False*, *vtype*: *Optional*[*type*] = *None*, *name*: *Optional*[*str*] = *None*, *tex\_name*=*None*, *info*=*None*)

Service for indicating an event for an extended, predefined period of time following the event disappearance.

The triggering of an event, whether the rise or fall edge, is specified through *trig*. For example, if *trig* = *rise*, the change of the input from 0 to 1 will be considered as an input, whereas the subsequent change back to 0 will be considered as the event end.

*ExtendedEvent.v* stores the flags whether the extended time has completed. Outputs will become 1 once the event starts and return to 0 when the extended time ends.

##### Parameters

**u** [v-provider] Triggering signal where the values are 0 or 1.

**trig** [str in ("rise", "fall")] Triggering edge for the beginning of an event. *rise* by default.

**enable** [bool or v-provider] If disabled, the output will be *v\_disabled*

**extend\_only** [bool] Only output during the extended period, not the event period.

**Warning:** The performance of this class needs to be optimized.

**class** andes.core.service.**VarHold**(*u*, *hold*, *vtype*=*None*, *name*=*None*, *tex\_name*=*None*, *info*=*None*)

Service for holding the input when the hold signal is on.

**Parameters**

**hold** [v-provider, binary] Hold signal array with length equal to the input. For elements that are 1, the corresponding inputs are held until the hold signal returns to 0.

**4.7.9 Flags**

```
class andes.core.service.FlagCondition(u, func, flag=1, name=None, tex_name=None,  
                                       info=None, cache=True)
```

Class for flagging values based on a condition function.

By default, values whose condition function output equal that equal to True/1 will be flagged as 1. 0 otherwise.

**Parameters**

**u** Input parameter

**func** A condition function that returns True or False.

**flag** [1 by default, only 0 or 1 is accepted.] The flag for the inputs whose condition output is True.

**Warning:** This class is not ready.

*FlagCondition* can only be applied to *BaseParam* with *cache=True*. Applying to *Service* will fail unless *cache* is False (at a performance cost).

```
class andes.core.service.FlagGreaterThan(u, value=0.0, flag=1, equal=False, name=None,  
                                          tex_name=None, info=None, cache=True)
```

Service for flagging parameters > or >= the given value element-wise.

Parameters that satisfy the comparison ( $u >$  or  $\geq$  value) will flagged as *flag* (1 by default).

```
class andes.core.service.FlagLessThan(u, value=0.0, flag=1, equal=False, name=None,  
                                       tex_name=None, info=None, cache=True)
```

Service for flagging parameters < or <= the given value element-wise.

Parameters that satisfy the comparison ( $u <$  or  $\leq$  value) will flagged as *flag* (1 by default).

```
class andes.core.service.FlagValue(u, value, flag=0, name=None, tex_name=None, info=None,  
                                   cache=True)
```

Class for flagging values that equal to the given value.

By default, values that equal to *value* will be flagged as 0. Non-matching values will be flagged as 1.

**Parameters**

**u** Input parameter

**value** Value to flag. Can be None, string, or a number.

**flag** [0 by default, only 0 or 1 is accepted.] The flag for the matched ones

**Warning:** *FlagNotNone* can only be applied to *BaseParam* with *cache=True*. Applying to *Service* will fail unless *cache* is *False* (at a performance cost).

#### 4.7.10 Data Select

**class** andes.core.service.DataSelect(*optional, fallback, name: Optional[str] = None, tex\_name: Optional[str] = None, info: Optional[str] = None*)

Class for selecting values for optional DataParam or NumParam.

This service is a v-provider that uses optional DataParam if available with a fallback.

DataParam will be tested for *None*, and NumParam will be tested with *np.isnan()*.

##### Notes

An use case of DataSelect is remote bus. One can do

```
self.buss = DataSelect(option=self.busr, fallback=self.bus)
```

Then, pass *self.buss* instead of *self.bus* as indexer to retrieve voltages.

Another use case is to allow an optional turbine rating. One can do

```
self.Tn = NumParam(default=None)
self.Sg = ExtParam(...)
self.Sn = DataSelect(Tn, Sg)
```

**class** andes.core.service.NumSelect(*optional, fallback, name: Optional[str] = None, tex\_name: Optional[str] = None, info: Optional[str] = None*)

Class for selecting values for optional NumParam.

NumSelect works with internal and external parameters.

##### Notes

One use case is to allow an optional turbine rating. One can do

```
self.Tn = NumParam(default=None)
self.Sg = ExtParam(...)
self.Sn = DataSelect(Tn, Sg)
```

### 4.7.11 Miscellaneous

```
class andes.core.service.InitChecker(u, lower=None, upper=None, equal=None,  
                                     not_equal=None, enable=True, error_out=False,  
                                     **kwargs)
```

Class for checking init values against known typical values.

Instances will be stored in *Model.services\_post* and *Model.services\_ichack*, which will be checked in *Model.post\_init\_check()* after initialization.

#### Parameters

**u** v-provider to be checked

**lower** [float, BaseParam, BaseVar, BaseService] lower bound

**upper** [float, BaseParam, BaseVar, BaseService] upper bound

**equal** [float, BaseParam, BaseVar, BaseService] values that the value from *v\_str* should equal

**not\_equal** [float, BaseParam, BaseVar, BaseService] values that should not equal

**enable** [bool] True to enable checking

#### Examples

Let's say generator excitation voltages are known to be in the range of 1.6 - 3.0 per unit. One can add the following instance to *GENBase*

```
self._vfc = InitChecker(u=self.vf,  
                        info='vf range',  
                        lower=1.8,  
                        upper=3.0,  
                        )
```

*lower* and *upper* can also take v-providers instead of float values.

One can also pass float values from Config to make it adjustable as in our implementation of *GENBase.\_vfc*.

```
class andes.core.service.ApplyFunc(u, func, name=None, tex_name=None, info=None,  
                                   cache=True)
```

Class for applying a numerical function on a parameter..

#### Parameters

**u** Input parameter

**func** A condition function that returns True or False.

**Warning:** This class is not ready.

```
class andes.core.service.CurrentSign(bus, bus1, bus2, name=None, tex_name=None,
                                     info=None)
```

Service for computing the sign of the current flowing through a series device.

With a given line connecting *bus1* and *bus2*, one can compute the current flow using  $(v1 \cdot \exp(1j \cdot a1) - v2 \cdot \exp(1j \cdot a2)) / (r + jx)$  whose value is the outflow on *bus1*.

*CurrentSign* can be used to compute the sign to be multiplied depending on the observing bus. For each value in *bus*, the sign will be +1 if it appears in *bus1* or -1 otherwise.

```
bus1          bus2
*----->>-----*
bus(+)        bus(-)
```

```
class andes.core.service.RandomService(func=<built-in method rand of
                                     numpy.random.mtrand.RandomState object>,
                                     **kwargs)
```

A service type for generating random numbers.

#### Parameters

**name** [str] Name

**func** [Callable] A callable for generating the random variable.

**Warning:** The value will be randomized every time it is accessed. Do not use it if the value needs to be stable for each simulation step.

```
class andes.core.service.SwBlock(*, init, ns, blocks, ext_sel=None, name=None, tex_name=None,
                                 info=None)
```

Service type for switched shunt blocks.

## 4.8 Discrete

### 4.8.1 Background

The discrete component library contains a special type of block for modeling the discontinuity in power system devices. Such continuities can be device-level physical constraints or algorithmic limits imposed on controllers.

The base class for discrete components is [\*andes.core.discrete.Discrete\*](#).

---

[\*Discrete\*](#)([name, tex\_name, info, no\_warn, ...])      Base discrete class.

---

**andes.core.discrete.Discrete**

```
class andes.core.discrete.Discrete(name=None, tex_name=None, info=None, no_warn=False,  
                                     min_iter=2, err_tol=0.01)
```

Base discrete class.

Discrete classes export flag arrays (usually boolean) .

```
__init__(name=None, tex_name=None, info=None, no_warn=False, min_iter=2, err_tol=0.01)
```

**Methods**

<code>check_eq(**kwargs)</code>	This function is called in <code>l_check_eq</code> after updating equations.
<code>check_iter_err</code> ([niter, err])	Check if the minimum iteration or maximum error is reached so that this discrete block should be enabled.
<code>check_var</code> (*args, **kwargs)	This function is called in <code>l_update_var</code> before evaluating equations.
<code>get_names()</code>	Available symbols from this class
<code>get_tex_names()</code>	Return <code>tex_names</code> of exported flags.
<code>get_values()</code>	
<code>list2array</code> (n)	Allocate memory for the discrete flags specified in <code>self.export_flags</code> .
<code>warn_init_limit()</code>	Warn if associated variables are initialized at limits.

**Discrete.check\_eq**

`Discrete.check_eq(**kwargs)`

This function is called in `l_check_eq` after updating equations.

It updates internal flags, set differential equations, and record pegged variables.

**Discrete.check\_iter\_err**

`Discrete.check_iter_err`(niter=None, err=None)

Check if the minimum iteration or maximum error is reached so that this discrete block should be enabled.

Only when both *niter* and *err* are given, ( $niter < min\_iter$ ) , and ( $err > err\_tol$ ) it will return False.

This logic will start checking the discrete states if called from an external solver that does not feed *niter* or *err* at each step.

**Returns**

**bool** True if it should be enabled, False otherwise

### Discrete.check\_var

`Discrete.check_var(*args, **kwargs)`

This function is called in `l_update_var` before evaluating equations.

It should update internal flags only.

#### Parameters

**adjust\_upper** [bool] True to adjust the upper limit to the value of the variable.  
Supported by limiters.

**adjust\_lower** [bool] True to adjust the lower limit to the value of the variable.  
Supported by limiters.

### Discrete.get\_names

`Discrete.get_names()`

Available symbols from this class

#### Returns

### Discrete.get\_tex\_names

`Discrete.get_tex_names()`

Return `tex_names` of exported flags.

TODO: Fix the bug described in the warning below.

#### Returns

**list** A list of `tex_names` for all exported flags.

**Warning:** If underscore `_` appears in both flag `tex_name` and `self.tex_name` (for example, when this discrete is within a block), the exported `tex_name` will become invalid for SymPy. Variable name substitution will fail.

**Discrete.get\_values**

Discrete.get\_values()

**Discrete.list2array**

Discrete.list2array(*n*)

Allocate memory for the discrete flags specified in *self.export\_flags*.

**Parameters**

**n** [int] Number of elements in the array. Provided by the calling function.

**Discrete.warn\_init\_limit**

Discrete.warn\_init\_limit()

Warn if associated variables are initialized at limits.

**Attributes**

---

*class\_name*

---

**Discrete.class\_name**

**property** Discrete.class\_name

The uniqueness of discrete components is the way it works. Discrete components take inputs, criteria, and exports a set of flags with the component-defined meanings. These exported flags can be used in algebraic or differential equations to build piece-wise equations.

For example, *Limiter* takes a v-provider as input, two v-providers as the upper and the lower bound. It exports three flags: *zi* (within bound), *zl* (below lower bound), and *zu* (above upper bound). See the code example in `models/pv.py` for an example voltage-based PQ-to-Z conversion.

It is important to note when the flags are updated. Discrete subclasses can use three methods to check and update the value and equations. Among these methods, *check\_var* is called *before* equation evaluation, but *check\_eq* and *set\_eq* are called *after* equation update. In the current implementation, *check\_var* updates flags for variable-based discrete components (such as *Limiter*). *check\_eq* updates flags for equation-involved discrete components (such as *AntiWindup*). *set\_var* is currently only used by *AntiWindup* to store the pegged states.

ANDES includes the following types of discrete components.

## 4.8.2 Limiters

```
class andes.core.discrete.Limiter(u, lower, upper, enable=True, name: Optional[str] = None,
                                tex_name: Optional[str] = None, info: Optional[str] = None,
                                min_iter: int = 2, err_tol: float = 0.01, allow_adjust: bool =
                                True, no_lower=False, no_upper=False, sign_lower=1,
                                sign_upper=1, equal=True, no_warn=False, zu=0.0, zl=0.0,
                                zi=1.0)
```

Base limiter class.

This class compares values and sets limit values. Exported flags are *zi*, *zl* and *zu*.

### Parameters

**u** [BaseVar] Input Variable instance

**lower** [BaseParam] Parameter instance for the lower limit

**upper** [BaseParam] Parameter instance for the upper limit

**no\_lower** [bool] True to only use the upper limit

**no\_upper** [bool] True to only use the lower limit

**sign\_lower: 1 or -1** Sign to be multiplied to the lower limit

**sign\_upper: bool** Sign to be multiplied to the upper limit

**equal** [bool] True to include equal signs in comparison ( $\geq$  or  $\leq$ ).

**no\_warn** [bool] Disable initial limit warnings

**zu** [0 or 1] Default value for *zu* if not enabled

**zl** [0 or 1] Default value for *zl* if not enabled

**zi** [0 or 1] Default value for *zi* if not enabled

### Notes

If not enabled, the default flags are  $zu = zl = 0$ ,  $zi = 1$ .

### Attributes

**zl** [array-like] Flags of elements violating the lower limit; A array of zeros and/or ones.

**zi** [array-like] Flags for within the limits

**zu** [array-like] Flags for violating the upper limit

```
class andes.core.discrete.SortedLimiter(u, lower, upper, n_select: int = 5, name=None,
                                       tex_name=None, enable=True, abs_violation=True,
                                       min_iter: int = 2, err_tol: float = 0.01, allow_adjust:
                                       bool = True, zu=0.0, zl=0.0, zi=1.0, ql=0.0, qu=0.0)
```

A limiter that sorts inputs based on the absolute or relative amount of limit violations.

### Parameters

**n\_select** [int] the number of violations to be flagged, for each of over-limit and under-limit cases. If *n\_select* == 1, at most one over-limit and one under-limit inputs will be flagged. If *n\_select* is zero, heuristics will be used.

**abs\_violation** [bool] True to use the absolute violation. False if the relative violation  $\text{abs}(\text{violation}/\text{limit})$  is used for sorting. Since most variables are in per unit, absolute violation is recommended.

```
class andes.core.discrete.HardLimiter(u, lower, upper, enable=True, name: Optional[str] =
    None, tex_name: Optional[str] = None, info:
    Optional[str] = None, min_iter: int = 2, err_tol: float =
    0.01, allow_adjust: bool = True, no_lower=False,
    no_upper=False, sign_lower=1, sign_upper=1,
    equal=True, no_warn=False, zu=0.0, zl=0.0, zi=1.0)
```

Hard limiter for algebraic or differential variable. This class is an alias of *Limiter*.

```
class andes.core.discrete.RateLimiter(u, lower, upper, enable=True, no_lower=False,
    no_upper=False, lower_cond=1, upper_cond=1,
    name=None, tex_name=None, info=None)
```

Rate limiter for a differential variable.

RateLimiter does not export any variable. It directly modifies the differential equation value.

**Warning:** RateLimiter cannot be applied to a state variable that already undergoes an AntiWindup limiter. Use *AntiWindupRate* for a rate-limited anti-windup limiter.

## Notes

RateLimiter inherits from Discrete to avoid internal naming conflicts with *Limiter*.

```
class andes.core.discrete.AntiWindup(u, lower, upper, enable=True, no_warn=False,
    no_lower=False, no_upper=False, sign_lower=1,
    sign_upper=1, name=None, tex_name=None, info=None,
    state=None, allow_adjust: bool = True)
```

Anti-windup limiter.

Anti-windup limiter prevents the wind-up effect of a differential variable. The derivative of the differential variable is reset if it continues to increase in the same direction after exceeding the limits. During the derivative return, the limiter will be inactive

```
if x > xmax and x dot > 0: x = xmax and x dot = 0
if x < xmin and x dot < 0: x = xmin and x dot = 0
```

This class takes one more optional parameter for specifying the equation.

### Parameters

**state** [State, ExtState] A State (or ExtState) whose equation value will be checked and, when condition satisfies, will be reset by the anti-windup-limiter.

```
class andes.core.discrete.AntiWindupRate(u, lower, upper, rate_lower, rate_upper,
                                         no_lower=False, no_upper=False,
                                         rate_no_lower=False, rate_no_upper=False,
                                         rate_lower_cond=None, rate_upper_cond=None,
                                         enable=True, name=None, tex_name=None,
                                         info=None, allow_adjust: bool = True)
```

Anti-windup limiter with rate limits

### 4.8.3 Comparers

```
class andes.core.discrete.LessThan(u, bound, equal=False, enable=True, name=None,
                                   tex_name=None, info: Optional[str] = None, cache: bool =
                                   False, z0=0, z1=1)
```

Less than (<) comparison function that tests if  $u < \text{bound}$ .

Exports two flags:  $z1$  and  $z0$ . For elements satisfying the less-than condition, the corresponding  $z1 = 1$ .  $z0$  is the element-wise negation of  $z1$ .

#### Notes

The default  $z0$  and  $z1$ , if not enabled, can be set through the constructor. By default, the model will not adjust the limit.

```
class andes.core.discrete.Selector(*args, fun, tex_name=None, info=None)
```

Selection between two variables using the provided reduce function.

The reduce function should take the given number of arguments. An example function is `np.maximum.reduce` which can be used to select the maximum.

Names are in  $s0$ ,  $s1$ .

**Warning:** A potential bug when more than two inputs are provided, and values in different inputs are equal. Only two inputs are allowed.

Deprecated since version 1.5.9: Use of this class for comparison-based output is discouraged. Instead, use *LessThan* and *Limiter* to construct pieewise equations.

See the new implementation of *HVGate* and *LVGate*.

See also:

`numpy.ufunc.reduce` NumPy reduce function

## Notes

A common pitfall is the 0-based indexing in the Selector flags. Note that exported flags start from 0. Namely, *s0* corresponds to the first variable provided for the Selector constructor.

## Examples

Example 1: select the largest value between *v0* and *v1* and put it into *vmax*.

After the definitions of *v0* and *v1*, define the algebraic variable *vmax* for the largest value, and a selector *vs*

```
self.vmax = Algeb(v_str='maximum(v0, v1)',
                 tex_name='v_{max}',
                 e_str='vs_s0 * v0 + vs_s1 * v1 - vmax')

self.vs = Selector(self.v0, self.v1, fun=np.maximum.reduce)
```

The initial value of *vmax* is calculated by `maximum(v0, v1)`, which is the element-wise maximum in SymPy and will be generated into `np.maximum(v0, v1)`. The equation of *vmax* is to select the values based on *vs\_s0* and *vs\_s1*.

```
class andes.core.discrete.Switcher(u, options: Union[list, Tuple], info: Optional[str] = None,
                                   name: Optional[str] = None, tex_name: Optional[str] =
                                   None, cache=True)
```

Switcher based on an input parameter.

The switch class takes one v-provider, compares the input with each value in the option list, and exports one flag array for each option. The flags are 0-indexed.

Exported flags are named with *\_s0*, *\_s1*, ..., with a total number of *len(options)*. See the examples section.

## Notes

Switches needs to be distinguished from Selector.

Switcher is for generating flags indicating option selection based on an input parameter. Selector is for generating flags at run time based on variable values and a selection function.

## Examples

The IEEEEST model takes an input for selecting the signal. Options are 1 through 6. One can construct

```
self.IC = NumParam(info='input code 1-6') # input code
self.SW = Switcher(u=self.IC, options=[0, 1, 2, 3, 4, 5, 6])
```

If the IC values from the data file ends up being

```
self.IC.v = np.array([1, 2, 2, 4, 6])
```

Then, the exported flag arrays will be

```
{'IC_s0': np.array([0, 0, 0, 0, 0]),
 'IC_s1': np.array([1, 0, 0, 0, 0]),
 'IC_s2': np.array([0, 1, 1, 0, 0]),
 'IC_s3': np.array([0, 0, 0, 0, 0]),
 'IC_s4': np.array([0, 0, 0, 1, 0]),
 'IC_s5': np.array([0, 0, 0, 0, 0]),
 'IC_s6': np.array([0, 0, 0, 0, 1])
}
```

where *IC\_s0* is used for padding so that following flags align with the options.

### 4.8.4 Deadband

```
class andes.core.discrete.DeadBand(u, center, lower, upper, enable=True, equal=False, zu=0.0,
                                   zl=0.0, zi=0.0, name=None, tex_name=None, info=None)
```

The basic deadband type.

#### Parameters

- u** [NumParam] The pre-deadband input variable
- center** [NumParam] Neutral value of the output
- lower** [NumParam] Lower bound
- upper** [NumParam] Upper bound
- enable** [bool] Enabled if True; Disabled and works as a pass-through if False.

## Notes

Input changes within a deadband will incur no output changes. This component computes and exports three flags.

### Three flags computed from the current input:

- **zl**: True if the input is below the lower threshold
- **zi**: True if the input is within the deadband
- **zu**: True if is above the lower threshold

Initial condition:

All three flags are initialized to zero. All flags are updated during *check\_var* when enabled. If the deadband component is not enabled, all of them will remain zero.

## Examples

Exported deadband flags need to be used in the algebraic equation corresponding to the post-deadband variable. Assume the pre-deadband input variable is *var\_in* and the post-deadband variable is *var\_out*. First, define a deadband instance *db* in the model using

```
self.db = DeadBand(u=self.var_in, center=self.dbc,
                  lower=self.dbl, upper=self.dbu)
```

To implement a no-memory deadband whose output returns to center when the input is within the band, the equation for *var* can be written as

```
var_out.e_str = 'var_in * (1 - db_zi) + \
                (dbc * db_zi) - var_out'
```

**class** andes.core.discrete.**DeadBandRT**(*u, center, lower, upper, enable=True*)

Deadband with flags for directions of return.

### Parameters

- u** [NumParam] The pre-deadband input variable
- center** [NumParam] Neutral value of the output
- lower** [NumParam] Lower bound
- upper** [NumParam] Upper bound
- enable** [bool] Enabled if True; Disabled and works as a pass-through if False.

## Notes

Input changes within a deadband will incur no output changes. This component computes and exports five flags. The additional two flags on top of *DeadBand* indicate the direction of return:

- zur: True if the input is/has been within the deadband and was returned from the upper threshold
- zlr: True if the input is/has been within the deadband and was returned from the lower threshold

Initial condition:

All five flags are initialized to zero. All flags are updated during *check\_var* when enabled. If the deadband component is not enabled, all of them will remain zero.

## Examples

To implement a deadband whose output is pegged at the nearest deadband bounds, the equation for *var* can be provided as

```
var_out.e_str = 'var_in * (1 - db_zi) + \
                dbl * db_zlr + \
                dbu * db_zur - var_out'
```

### 4.8.5 Others

**class** andes.core.discrete.**Average**(*u, mode='step', delay=0, name=None, tex\_name=None, info=None*)

Compute the average of a BaseVar over a period of time or a number of samples.

**class** andes.core.discrete.**Delay**(*u, mode='step', delay=0, name=None, tex\_name=None, info=None*)

Delay class to memorize past variable values.

Delay allows to impose a predefined "delay" (in either steps or seconds) for an input variable. The amount of delay is a scalar and has to be fixed at model definition in the current implementation.

**class** andes.core.discrete.**Derivative**(*u, name=None, tex\_name=None, info=None*)

Compute the derivative of an algebraic variable using numerical differentiation.

**class** andes.core.discrete.**Sampling**(*u, interval=1.0, offset=0.0, name=None, tex\_name=None, info=None*)

Sample an input variable repeatedly at a given time interval.

**class** andes.core.discrete.**ShuntAdjust**(*\*, v, lower, upper, bsw, gsw, dt, u, enable=True, min\_iter=2, err\_tol=0.01, name=None, tex\_name=None, info=None, no\_warn=False*)

Class for adjusting switchable shunts.

#### Parameters

**v** [BaseVar] Voltage measurement

**lower** [BaseParam] Lower voltage bound  
**upper** [BaseParam] Upper voltage bound  
**bsw** [SwBlock] SwBlock instance for susceptance  
**gsw** [SwBlock] SwBlock instance for conductance  
**dt** [NumParam] Delay time  
**u** [NumParam] Connection status  
**min\_iter** [int] Minimum iteration number to enable shunt switching  
**err\_tol** [float] Minimum iteration tolerance to enable switching

## 4.9 Blocks

### 4.9.1 Background

The block library contains commonly used blocks (such as transfer functions and nonlinear functions). Variables and equations are pre-defined for blocks to be used as "lego pieces" for scripting DAE models. The base class for blocks is `andes.core.block.Block`.

The supported blocks include `Lag`, `LeadLag`, `Washout`, `LeadLagLimit`, `PIController`. In addition, the base class for piece-wise nonlinear functions, `PieceWise` is provided. `PieceWise` is used for implementing the quadratic saturation function `MagneticQuadSat` and exponential saturation function `MagneticExpSat`.

All variables in a block must be defined as attributes in the constructor, just like variable definition in models. The difference is that the variables are "exported" from a block to the capturing model. All exported variables need to be placed in a dictionary, `self.vars` at the end of the block constructor.

Blocks can be nested as advanced usage. See the following API documentation for more details.

**class** `andes.core.block.Block`(*name: Optional[str] = None, tex\_name: Optional[str] = None, info: Optional[str] = None, namespace: str = 'local'*)

Base class for control blocks.

Blocks are meant to be instantiated as Model attributes to provide pre-defined equation sets. Subclasses must overload the `__init__` method to take custom inputs. Subclasses of `Block` must overload the `define` method to provide initialization and equation strings. Exported variables, services and blocks must be constructed into a dictionary `self.vars` at the end of the constructor.

Blocks can be nested. A block can have blocks but itself as attributes and therefore reuse equations. When a block has sub-blocks, the outer block must be constructed with a ``name``.

Nested block works in the following way: the parent block modifies the sub-block's `name` attribute by prepending the parent block's name at the construction phase. The parent block then exports the sub-block as a whole. When the parent Model class picks up the block, it will recursively import the variables in the block and the sub-blocks correctly. See the example section for details.

#### Parameters

**name** [str, optional] Block name

**tex\_name** [str, optional] Block LaTeX name

**info** [str, optional] Block description.

**namespace** [str, local or parent] Namespace of the exported elements. If 'local', the block name will be prepended by the parent. If 'parent', the original element name will be used when exporting.

**Warning:** It is a good practice to avoid more than one level of nesting, to avoid multi-underscore variable names.

## Examples

Example for two-level nested blocks. Suppose we have the following hierarchy

```
SomeModel  instance M
|
LeadLag A  exports (x, y)
|
Lag B      exports (x, y)
```

SomeModel instance M contains an instance of LeadLag block named A, which contains an instance of a Lag block named B. Both A and B exports two variables x and y.

In the code of Model, the following code is used to instantiate LeadLag

```
class SomeModel:
    def __init__(...)
        ...
        self.A = LeadLag(name='A',
                          u=self.foo1,
                          T1=self.foo2,
                          T2=self.foo3)
```

To use Lag in the LeadLag code, the following lines are found in the constructor of LeadLag

```
class LeadLag:
    def __init__(name, ...)
        ...
        self.B = Lag(u=self.y, K=self.K, T=self.T)
        self.vars = {..., 'A': self.A}
```

The `__setattr__` magic of LeadLag takes over the construction and assigns `A_B` to `B.name`, given A's name provided at run time. `self.A` is exported with the internal name A at the end.

Again, the LeadLag instance name (A in this example) MUST be provided in *SomeModel*'s constructor for the name prepending to work correctly. If there is more than one level of nesting, other than the leaf-level block, all parent blocks' names must be provided at instantiation.

When A is picked up by *SomeModel.\_\_setattr\_\_*, B is captured from A's exports. Recursively, B's variables are exported, Recall that *B.name* is now A\_B, following the naming rule (parent block's name + variable name), B's internal variables become A\_B\_x and A\_B\_y.

In this way, B's *define()* needs no modification since the naming rule is the same. For example, B's internal y is always {*self.name*}\_y, although B has gotten a new name A\_B.

## 4.9.2 Transfer Functions

The following transfer function blocks have been implemented. They can be imported to build new models.

### Algebraic

**class** andes.core.block.**Gain**(*u, K, name=None, tex\_name=None, info=None*)

Gain block.

$$u \rightarrow \boxed{K} \rightarrow y$$

Exports an algebraic output y.

**define()**

Implemented equation and the initial condition are

$$\begin{aligned} y &= Ku \\ y^{(0)} &= Ku^{(0)} \end{aligned}$$

### First Order

**class** andes.core.block.**Integrator**(*u, T, K, y0, check\_init=True, name=None, tex\_name=None, info=None*)

Integrator block.

$$u \rightarrow \boxed{K/sT} \rightarrow y$$

Exports a differential variable y.

The initial output needs to be specified through y0.

**define()**

Implemented equation and the initial condition are

$$\begin{aligned} \dot{y} &= Ku \\ y^{(0)} &= 0 \end{aligned}$$

```
class andes.core.block.IntegratorAntiWindup(u, T, K, y0, lower, upper, name=None,  
                                             tex_name=None, info=None, no_warn=False)
```

Integrator block with anti-windup limiter.

Exports a differential variable  $y$  and an AntiWindup *lim*. The initial output must be specified through  $y0$ .

**define()**

Implemented equation and the initial condition are

$$\dot{y} = Ku$$

$$y^{(0)} = 0$$

```
class andes.core.block.Lag(u, T, K, D=1, name=None, tex_name=None, info=None)
```

Lag (low pass filter) transfer function.

Exports one state variable  $y$  as the output.

#### Parameters

**K** Gain

**T** Time constant

**D** Constant

**u** Input variable

**define()**

## Notes

Equations and initial values are

$$T\dot{y} = (Ku - Dy)$$

$$y^{(0)} = Ku/D$$

**class** andes.core.block.LagAntiWindup(*u, T, K, lower, upper, D=1, name=None, tex\_name=None, info=None*)

Lag (low pass filter) transfer function block with an anti-windup limiter.

Exports one state variable  $y$  as the output and one AntiWindup instance  $lim$ .

## Parameters

- K** Gain
- T** Time constant
- D** Constant
- u** Input variable

**define()**

## Notes

Equations and initial values are

$$T\dot{y} = (Ku - Dy)$$

$$y^{(0)} = Ku/D$$

**class** andes.core.block.Washout(*u, T, K, name=None, tex\_name=None, info=None*)

Washout filter (high pass) block.

Exports state  $x$  (symbol  $x'$ ) and output algebraic variable  $y$ .

**define()**

### Notes

Equations and initial values:

$$\begin{aligned}Tx' &= (u - x') \\Ty &= K(u - x') \\x'^{(0)} &= u \\y^{(0)} &= 0\end{aligned}$$

**class** andes.core.block.WashoutOrLag( $u, T, K, name=None, zero\_out=True, tex\_name=None, info=None$ )

Washout with the capability to convert to Lag when  $K = 0$ .

Can be enabled with *zero\_out*. Need to provide *name* to construct.

Exports state  $x$  (symbol  $x'$ ), output algebraic variable  $y$ , and a LessThan block *LT*.

### Parameters

**zero\_out** [bool, optional] If True, *sT* will become 1, and the washout will become a low-pass filter. If False, functions as a regular Washout.

**define()**

### Notes

Equations and initial values:

$$\begin{aligned}Tx' &= (u - x') \\Ty &= z_0 K(u - x') + z_1 Tx \\x'^{(0)} &= u \\y^{(0)} &= 0\end{aligned}$$

where  $z_0$  is a flag array for the greater-than-zero elements, and  $z_1$  is that for the less-than or equal-to zero elements.

**class** andes.core.block.LeadLag( $u, T1, T2, K=1, zero\_out=True, name=None, tex\_name=None, info=None$ )

Lead-Lag transfer function block in series implementation

$$u \rightarrow \left[ K \frac{1 + sT1}{1 + sT2} \right] \rightarrow y$$

Exports two variables: internal state  $x$  and output algebraic variable  $y$ .

### Parameters

**T1** [BaseParam] Time constant 1

**T2** [BaseParam] Time constant 2

**zero\_out** [bool] True to allow zeroing out lead-lag as a pass through (when T1=T2=0)

### Notes

To allow zeroing out lead-lag as a pure gain, set **zero\_out** to *True*.

**define()**

### Notes

Implemented equations and initial values

$$\begin{aligned}
 T_2 \dot{x}' &= (u - x') \\
 T_2 y &= K T_1 (u - x') + K T_2 x' + E_2, \text{ where} \\
 E_2 &= \begin{cases} (y - K x') & \text{if } T_1 = T_2 = 0 \& \text{zero\_out} = \text{True} \\ 0 & \text{otherwise} \end{cases} \\
 x'^{(0)} &= u \\
 y^{(0)} &= K u
 \end{aligned}$$

**class** andes.core.block.**LeadLagLimit**( $u, T1, T2, lower, upper, name=None, tex\_name=None, info=None$ )

Lead-Lag transfer function block with hard limiter (series implementation)

Exports four variables: state  $x$ , output before hard limiter  $ynl$ , output  $y$ , and AntiWindup  $lim$ .

**define()**

## Notes

Implemented control block equations (without limiter) and initial values

$$\begin{aligned}T_2 \dot{x}' &= (u - x') \\T_2 y &= T_1(u - x') + T_2 x' \\x'^{(0)} &= y^{(0)} = u\end{aligned}$$

## Second Order

**class** andes.core.block.Lag2ndOrd(*u, K, T1, T2, name=None, tex\_name=None, info=None*)  
Second order lag transfer function (low-pass filter)

Exports one two state variables (*x, y*), where *y* is the output.

### Parameters

**u** Input

**K** Gain

**T1** First order time constant

**T2** Second order time constant

**define()**

## Notes

Implemented equations and initial values are

$$\begin{aligned}T_2 \dot{x} &= Ku - y - T_1 x \\ \dot{y} &= x \\ x^{(0)} &= 0 \\ y^{(0)} &= Ku\end{aligned}$$

**class** andes.core.block.LeadLag2ndOrd(*u, T1, T2, T3, T4, zero\_out=False, name=None, tex\_name=None, info=None*)  
Second-order lead-lag transfer function block

$$u \rightarrow \left[ \frac{1 + sT_3 + s^2 T_4}{1 + sT_1 + s^2 T_2} \right] \rightarrow y$$

Exports two internal states ( $x_1$  and  $x_2$ ) and output algebraic variable  $y$ .

# TODO: instead of implementing *zero\_out* using *LessThan* and an additional term, consider correcting all parameters to 1 if all are 0.

**define()**

### Notes

Implemented equations and initial values are

$$\begin{aligned} T_2 \dot{x}_1 &= u - x_2 - T_1 x_1 \\ \dot{x}_2 &= x_1 \\ T_2 y &= T_2 x_2 + T_2 T_3 x_1 + T_4 (u - x_2 - T_1 x_1) + E_2, \text{ where} \\ E_2 &= \begin{cases} (y - x_2) & \text{if } T_1 = T_2 = T_3 = T_4 = 0 \& \text{zero\_out} = \text{True} \\ 0 & \text{otherwise} \end{cases} \\ x_1^{(0)} &= 0 \\ x_2^{(0)} = y^{(0)} &= u \end{aligned}$$

### 4.9.3 Saturation

**class** andes.models.exciter.**ExcExpSat**(*E1*, *SE1*, *E2*, *SE2*, *name=None*, *tex\_name=None*, *info=None*)

Exponential exciter saturation block to calculate A and B from E1, SE1, E2 and SE2. Input parameters will be corrected and the user will be warned. To disable saturation, set either E1 or E2 to 0.

#### Parameters

**E1** [BaseParam] First point of excitation field voltage

**SE1: BaseParam** Coefficient corresponding to E1

**E2** [BaseParam] Second point of excitation field voltage

**SE2: BaseParam** Coefficient corresponding to E2

**define()**

## Notes

The implementation solves for coefficients  $A$  and  $B$  which satisfy

$$E_1 S_{E1} = A e^{E_1 \times B} E_2 S_{E2} = A e^{E_2 \times B}$$

The solutions are given by

$$E_1 S_{E1} e^{\frac{E_1 \log\left(\frac{E_2 S_{E2}}{E_1 S_{E1}}\right)}{E_1 - E_2}} - \frac{\log\left(\frac{E_2 S_{E2}}{E_1 S_{E1}}\right)}{E_1 - E_2}$$

## 4.9.4 Others

### Value Selector

**class** andes.core.block.HVGate( $u1, u2, name=None, tex\_name=None, info=None$ )

High Value Gate. Outputs the maximum of two inputs.

**class** andes.core.block.LVGate( $u1, u2, name=None, tex\_name=None, info=None$ )

Low Value Gate. Outputs the minimum of the two inputs.

## 4.9.5 Naming Convention

We loosely follow a naming convention when using modeling blocks. An instance of a modeling block is named with a two-letter acronym, followed by a number or a meaningful but short variable name. The acronym and the name are spelled in one word without underscore, as the output of the block already contains  $-y$ .

For example, two washout filters can be names W01 and W02. In another case, a first-order lag function for voltage sensing can be called LGv, or even LG if there is only one Lag instance in the model.

Naming conventions are not strictly enforced. Expressiveness and concision are encouraged.

## 4.10 Examples

We show two examples to demonstrate modeling from equations and modeling from control block diagrams.

- The TGOV1 example shows code snippet for equation-based modeling and, as well as code for block-based modeling.
- The IEEEEST example walks through the source code and explains the complete setup, including optional parameters, input selection, and manual per-unit conversion.

### 4.10.1 TGOV1

The *TGOV1* turbine governor model is shown as a practical example using the library.

This model is composed of a lead-lag transfer function and a first-order lag transfer function with an anti-windup limiter, which are sufficiently complex for demonstration. The corresponding differential equations and algebraic equations are given below.

$$\begin{bmatrix} \dot{x}_{LG} \\ \dot{x}_{LL} \end{bmatrix} = \begin{bmatrix} z_{i,lim}^{LG} (P_d - x_{LG}) / T_1 \\ (x_{LG} - x_{LL}) / T_3 \end{bmatrix}$$

$$\begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} (1 - \omega) - \omega_d \\ R \times \tau_{m0} - P_{ref} \\ (P_{ref} + \omega_d) / R - P_d \\ D_t \omega_d + y_{LL} - P_{OUT} \\ \frac{T_2}{T_3} (x_{LG} - x_{LL}) + x_{LL} - y_{LL} \\ u (P_{OUT} - \tau_{m0}) \end{bmatrix}$$

where *LG* and *LL* denote the lag block and the lead-lag block,  $\dot{x}_{LG}$  and  $\dot{x}_{LL}$  are the internal states,  $y_{LL}$  is the lead-lag output,  $\omega$  the generator speed,  $\omega_d$  the generator under-speed,  $P_d$  the droop output,  $\tau_{m0}$  the steady-state torque input, and  $P_{OUT}$  the turbine output that will be summed at the generator.

The code to describe the above model using equations is given below. The complete code can be found in class `TGOV1ModelAlt` in `andes/models/governor.py`.

```
def __init__(self, system, config):
    # 1. Declare parameters from case file inputs.
```

(continues on next page)

(continued from previous page)

```

self.R = NumParam(info='Turbine governor droop',
                  non_zero=True, ipower=True)
# Other parameters are omitted.

# 2. Declare external variables from generators.
self.omega = ExtState(src='omega',
                      model='SynGen',
                      indexer=self.syn,
                      info='Generator speed')
self.tm = ExtAlgeb(src='tm',
                  model='SynGen',
                  indexer=self.syn,
                  e_str='u*(pout-tm0)',
                  info='Generator torque input')

# 3. Declare initial values from generators.
self.tm0 = ExtService(src='tm',
                     model='SynGen',
                     indexer=self.syn,
                     info='Initial torque input')

# 4. Declare variables and equations.
self.pref = Algeb(info='Reference power input',
                  v_str='tm0*R',
                  e_str='tm0*R-pref')
self.wd = Algeb(info='Generator under speed',
                e_str='(1-omega)-wd')
self.pd = Algeb(info='Droop output',
                v_str='tm0',
                e_str='(wd+pref)/R-pd')
self.LG_x = State(info='State in the lag TF',
                  v_str='pd',
                  e_str='LG_lim_zi*(pd-LG_x)/T1')
self.LG_lim = AntiWindup(u=self.LG_x,
                        lower=self.VMIN,
                        upper=self.VMAX)
self.LL_x = State(info='State in the lead-lag TF',
                  v_str='LG_x',
                  e_str='(LG_x-LL_x)/T3')
self.LL_y = Algeb(info='Lead-lag Output',
                  v_str='LG_x',
                  e_str='T2/T3*(LG_x-LL_x)+LL_x-LL_y')
self.pout = Algeb(info='Turbine output power',
                  v_str='tm0',
                  e_str='(LL_y+Dt*wd)-pout')

```

Another implementation of *TGOV1* makes extensive use of the modeling blocks. The resulting code is more readable as follows.

```
def __init__(self, system, config):
    TGBase.__init__(self, system, config)

    self.gain = ConstService(v_str='u/R')

    self.pref = Algeb(info='Reference power input',
                      tex_name='P_{ref}',
                      v_str='tm0 * R',
                      e_str='tm0 * R - pref',
                      )

    self.wd = Algeb(info='Generator under speed',
                    unit='p.u.',
                    tex_name=r'\omega_{dev}',
                    v_str='0',
                    e_str='(wref - omega) - wd',
                    )

    self.pd = Algeb(info='Pref plus under speed times gain',
                    unit='p.u.',
                    tex_name="P_d",
                    v_str='u * tm0',
                    e_str='u*(wd + pref + paux) * gain - pd')

    self.LAG = LagAntiWindup(u=self.pd,
                              K=1,
                              T=self.T1,
                              lower=self.VMIN,
                              upper=self.VMAX,
                              )

    self.LL = LeadLag(u=self.LAG.y,
                      T1=self.T2,
                      T2=self.T3,
                      )

    self.pout.e_str = '(LL_y + Dt * wd) - pout'
```

The complete code can be found in class `TGOV1Model` in `andes/models/governor.py`.

### 4.10.2 IEEEEST

In this example, we will explain step-by-step how *IEEEEST* is programmed. The block diagram of IEEEEST is given as follows. We recommend you to open up the source code in `andes/models/pss.py` and then continue reading.

First of all, modeling components are imported at the beginning.

Next, `PSSBaseData` is defined to hold parameters shared by all PSSs. `PSSBaseData` inherits from `ModelData` and calls the base constructor. There is only one field `avr` defined for the linked exciter idx.

Then, `IEEEESTData` defines the input parameters for IEEEEST. Use `IdxParam` for fields that store idx-es of devices that IEEEEST devices link to. Use `NumParam` for numerical parameters.

### PSSBase

`PSSBase` is defined for the common (external) parameters, services and variables shared by all PSSs. The class and constructor signatures are

```
class PSSBase(Model):
    def __init__(self, system, config):
        super().__init__(system, config)
```

`PSSBase` inherits from `Model` and calls the base constructor. Note that the call to `Model`'s constructor takes two positional arguments, `system` and `config` of types `System` and `ModelConfig`. Next, the group is specified, and the model flags are set.

```
self.group = 'PSS'
self.flags.update({'tds': True})
```

Next, `Replace` is used to replace input parameters that satisfy a lambda function with new values.

```
self.VCUr = Replace(self.VCU, lambda x: np.equal(x, 0.0), 999)
self.VCLr = Replace(self.VCL, lambda x: np.equal(x, 0.0), -999)
```

The value replacement happens when `VCUr` and `VCLr` is first accessed. `Replace` is executed in the model initialization phase (at the end of services update).

Next, the indices of connected generators, buses, and bus frequency measurements are retrieved. Synchronous generator idx is retrieved with

```
self.syn = ExtParam(model='Exciter', src='syn', indexer=self.avr, export=False,
                    info='Retrieved generator idx', vtype=str)
```

Using the retrieved `self.syn`, it retrieves the buses to which the generators are connected.

```
self.bus = ExtParam(model='SynGen', src='bus', indexer=self.syn, export=False,
                    info='Retrieved bus idx', vtype=str, default=None,
                    )
```

PSS models support an optional remote bus specified through parameter `busr`. When `busr` is `None`, the generator-connected bus should be used. The following code uses `DataSelect` to select `busr` if available but falls back to `bus` otherwise.

```
self.buss = DataSelect(self.busr, self.bus, info='selected bus (bus or busr)')
```

Each PSS links to a bus frequency measurement device. If the input data does not specify one or the specified one does not exist, `DeviceFinder` can find the correct measurement device for the bus where frequency measurements should be taken.

```
self.busfreq = DeviceFinder(self.busf, link=self.buss, idx_name='bus')
```

where `busf` is the optional frequency measurement device idx, `buss` is the bus idx for which measurement device needs to be found or created.

Next, external parameters, variables and services are retrieved. Note that the PSS output `vsout` is pre-allocated but the equation string is left to specific models.

## IEEEESTModel

`IEEEESTModel` inherits from `PSSBase` and adds specific model components. After calling `PSSBase`'s constructor, `IEEEESTModel` adds config entries to allow specifying the model for frequency measurement, because there may be multiple frequency measurement models in the future.

```
self.config.add(OrderedDict([('freq_model', 'BusFreq'])))
self.config.add_extra('_help', {'freq_model': 'default freq. measurement model'})
self.config.add_extra('_alt', {'freq_model': ('BusFreq',)})
```

We set the chosen measurement model to `busf` so that `DeviceFinder` knows which model to use if it needs to create new devices.

```
self.busf.model = self.config.freq_model
```

Next, because bus voltage is an algebraic variable, we use `Derivative` to calculate the finite difference to approximate its derivative.

```
self.dv = Derivative(self.v, tex_name='dV/dt', info='Finite difference of bus_
↪voltage')
```

Then, we retrieve the coefficient to convert power from machine base to system base using `ConstService`, given by  $S_b / S_n$ . This is needed for input mode 3, electric power in machine base.

```
self.SnSb = ExtService(model='SynGen', src='M', indexer=self.syn, attr='pu_coeff
↪',
                        info='Machine base to sys base factor for power',
                        tex_name='(Sb/Sn)')
```

Note that the `ExtService` access the `pu_coeff` field of the `M` variables of synchronous generators. Since `M` is a machine-base power quantity, `M.pu_coeff` stores the multiplication coefficient to convert each of them from machine bases to the system base, which is  $S_b / S_n$ .

The input mode is parsed into boolean flags using `Switcher`:

```
self.SW = Switcher(u=self.MODE,
                   options=[0, 1, 2, 3, 4, 5, 6],
                   )
```

where the input `u` is the `MODE` parameter, and `options` is a list of accepted values. `Switcher` boolean arrays `s0`, `s1`, ..., `sN`, where  $N = \text{len}(\text{options}) - 1$ . We added `0` to `options` for padding so that `SW_s1` corresponds to `MODE 1`. It improves the readability of the code as we will see next.

The input signal `sig` is an algebraic variable given by

```
self.sig = Algeb(tex_name='S_{ig}',
                 info='Input signal',
                 )

self.sig.v_str = 'SW_s1*(omega-1) + SW_s2*0 + SW_s3*(tm0/SnSb) + ' \
                 'SW_s4*(tm-tm0) + SW_s5*v + SW_s6*0'

self.sig.e_str = 'SW_s1*(omega-1) + SW_s2*(f-1) + SW_s3*(te/SnSb) + ' \
                 'SW_s4*(tm-tm0) + SW_s5*v + SW_s6*dv_v - sig'
```

The `v_str` and `e_str` are separated from the constructor to improve readability. They construct piece-wise functions to select the correct initial values and equations based on mode. For any variables in `v_str`, they must be defined before `sig` so that they will be initialized ahead of `sig`. Clearly, `omega`, `tm`, and `v` are defined in `PSSBase` and thus come before `sig`.

The following comes the most effective part: modeling using transfer function blocks. We utilized several blocks to describe the model from the diagram. Note that the output of a block is always the block name followed by `_y`. For example, the input of `F2` is the output of `F1`, given by `F1_y`.

```
self.F1 = Lag2ndOrd(u=self.sig, K=1, T1=self.A1, T2=self.A2)

self.F2 = LeadLag2ndOrd(u=self.F1_y, T1=self.A3, T2=self.A4,
```

(continues on next page)

(continued from previous page)

```

        T3=self.A5, T4=self.A6, zero_out=True)

self.LL1 = LeadLag(u=self.F2_y, T1=self.T1, T2=self.T2, zero_out=True)

self.LL2 = LeadLag(u=self.LL1_y, T1=self.T3, T2=self.T4, zero_out=True)

self.Vks = Gain(u=self.LL2_y, K=self.KS)

self.WO = WashoutOrLag(u=self.Vks_y, T=self.T6, K=self.T5, name='WO',
                        zero_out=True) # WO_y == Vss

self.VLIM = Limiter(u=self.WO_y, lower=self.LSMIN, upper=self.LSMAX,
                    info='Vss limiter')

self.Vss = Algeb(tex_name='V_{ss}', info='Voltage output before output limiter',
                 e_str='VLIM_zi * WO_y + VLIM_zu * LSMAX + VLIM_zl * LSMIN - Vss
→')

self.OLIM = Limiter(u=self.v, lower=self.VCLr, upper=self.VCUr,
                    info='output limiter')

self.vsout.e_str = 'OLIM_zi * Vss - vsout'

```

In the end, the output equation is assigned to `vsout.e_str`. It completes the equations of the IEEEEST model.

## Finalize

Assemble IEEEESTData and IEEEESTModel into IEEEEST:

```

class IEEEEST(IEEEESTData, IEEEESTModel):
    def __init__(self, system, config):
        IEEEESTData.__init__(self)
        IEEEESTModel.__init__(self, system, config)

```

Locate `andes/models/__init__.py`, in `file_classes`, find the key `pss` and add `IEEEEST` to its value list. In `file_classes`, keys are the `.py` file names under the folder `models`, and values are class names to be imported from that file. If the file name does not exist as a key in `file_classes`, add it after all prerequisite models. For example, `PSS` should be added after `exciters` (and `generators`, of course).

Finally, locate `andes/models/group.py`, check if the class with `PSS` exist. It is the name of `IEEEEST`'s group name. If not, create one by inheriting from `GroupBase`:

```

class PSS(GroupBase):
    """Power system stabilizer group."""

```

(continues on next page)

(continued from previous page)

```
def __init__(self):  
    super().__init__()  
    self.common_vars.extend(('vsout',))
```

where we added `vsout` to the `common_vars` list. All models in the PSS group must have a variable named `vsout`, which is defined in `PSSBase`.

This completes the IEEEEST model. When developing new models, use `andes prepare` to generate numerical code and start debugging.

##### reload\_submodules

`andes.system.reload_submodules(module_name)`  
Helper function for reloading an existing module and its submodules.  
It is used to reload the pycode module after regenerating code.

## Classes

---

<i>ExistingModels</i> ()	Storage class for existing models
<i>System</i> ([case, name, config, config_path, ...])	System contains models and routines for modeling and simulation.

---

### andes.system.ExistingModels

**class** andes.system.ExistingModels

Storage class for existing models

`__init__()`

#### Methods

—

### andes.system.System

**class** andes.system.System(*case*: *Optional[str]* = None, *name*: *Optional[str]* = None, *config*: *Optional[Dict]* = None, *config\_path*: *Optional[str]* = None, *default\_config*: *Optional[bool]* = False, *options*: *Optional[Dict]* = None, *no\_undill*: *Optional[bool]* = False, *\*\*kwargs*)

System contains models and routines for modeling and simulation.

System contains a several special *OrderedDict* member attributes for housekeeping. These attributes include *models*, *groups*, *routines* and *calls* for loaded models, groups, analysis routines, and generated numerical function calls, respectively.

#### Parameters

**no\_undill** [bool, optional] True to disable the call to `System.undill()` at the end of object creation. False by default.

## Notes

System stores model and routine instances as attributes. Model and routine attribute names are the same as their class names. For example, *Bus* is stored at `system.Bus`, the power flow calculation routine is at `system.PFlow`, and the numerical DAE instance is at `system.dae`. See attributes for the list of attributes.

#### Attributes

**dae** [andes.variables.dae.DAE] Numerical DAE storage

**files** [andes.variables.fileman.FileMan] File path storage

**config** [andes.core.Config] System config storage

**models** [OrderedDict] model name and instance pairs

**groups** [OrderedDict] group name and instance pairs

**routes** [OrderedDict] routine name and instance pairs

**\_\_init\_\_** (case: *Optional[str]* = None, name: *Optional[str]* = None, config: *Optional[Dict]* = None, config\_path: *Optional[str]* = None, default\_config: *Optional[bool]* = False, options: *Optional[Dict]* = None, no\_undill: *Optional[bool]* = False, \*\*kwargs)

## Methods

<code>add(model[, param_dict])</code>	Add a device instance for an existing model.
<code>as_dict([vin, skip_empty])</code>	Return system data as a dict where the keys are model names and values are dicts.
<code>calc_pu_coeff()</code>	Perform per unit value conversion.
<code>call_models(method, models, *args, **kwargs)</code>	Call methods on the given models.
<code>collect_ref()</code>	Collect indices into <i>BackRef</i> for all models.
<code>connectivity([info])</code>	Perform connectivity check for system.
<code>dill()</code>	Serialize generated numerical functions in <code>System.calls</code> with package <code>dill</code> .
<code>e_clear(models)</code>	Clear equation arrays in DAE and model variables.
<code>f_update(models)</code>	Call the differential equation update method for models in sequence.
<code>fg_to_dae()</code>	Collect equation values into the DAE arrays.
<code>find_devices()</code>	Add dependent devices for all model based on <i>DeviceFinder</i> .
<code>find_models(flag[, skip_zero])</code>	Find models with at least one of the flags as True.
<code>fix_address()</code>	Fixes addressing issues after loading a snapshot.
<code>from_ipysheet(model, sheet[, vin])</code>	Set an ipysheet object back to model.
<code>g_islands()</code>	Reset algebraic mismatches for islanded buses.
<code>g_update(models)</code>	Call the algebraic equation update method for models in sequence.
<code>get_config()</code>	Collect config data from models.
<code>get_z(models)</code>	Get all discrete status flags in a numpy array.
<code>import_groups()</code>	Import all groups classes defined in <code>devices/group.py</code> .
<code>import_models()</code>	Import and instantiate models as <code>System</code> member attributes.
<code>import_routines()</code>	Import routines as defined in <code>routines/__init__.py</code> .
<code>init(models, routine)</code>	Initialize the variables for each of the specified models.

continues on next page

Table 5 – continued from previous page

<code>j_islands()</code>	Set gy diagonals to eps for <i>a</i> and <i>v</i> variables of islanded buses.
<code>j_update(models[, info])</code>	Call the Jacobian update method for models in sequence.
<code>l_update_eq(models[, init])</code>	Update equation-dependent limiter discrete components by calling <code>l_check_eq</code> of models.
<code>l_update_var(models[, niter, err])</code>	Update variable-based limiter discrete states by calling <code>l_update_var</code> of models.
<code>link_ext_param([model])</code>	Retrieve values for <code>ExtParam</code> for the given models.
<code>load_config([conf_path])</code>	Load config from an rc-formatted file.
<code>precompile([models, nomp, ncpu])</code>	Trigger precompilation for the given models.
<code>prepare([quick, incremental, models, nomp, ncpu])</code>	Generate numerical functions from symbolically defined models.
<code>reload(case, **kwargs)</code>	Reload a new case in the same System object.
<code>remove_pycapsule()</code>	Remove PyCapsule objects in solvers.
<code>reset([force])</code>	Reset to the state after reading data and setup (before power flow).
<code>s_update_post(models)</code>	Update variable services by calling <code>s_update_post</code> of models.
<code>s_update_var(models)</code>	Update variable services by calling <code>s_update_var</code> of models.
<code>save_config([file_path, overwrite])</code>	Save all system, model, and routine configurations to an rc-formatted file.
<code>set_address(models)</code>	Set addresses for differential and algebraic variables.
<code>set_config([config])</code>	Set configuration for the System object.
<code>set_dae_names(models)</code>	Set variable names for differential and algebraic variables, right-hand side of external equations, and discrete flags.
<code>set_var_arrays(models[, inplace, alloc])</code>	Set arrays ( <i>v</i> and <i>e</i> ) for internal variables to access dae arrays in place.
<code>setup()</code>	Set up system for studies.
<code>store_adder_setter(models)</code>	Store non-inplace adders and setters for variables and equations.
<code>store_existing()</code>	Store existing models in <i>System.existing</i> .
<code>store_no_check_init(models)</code>	Store differential variables with <code>check_init == False</code> .
<code>store_sparse_pattern(models)</code>	Collect and store the sparsity pattern of Jacobian matrices.
<code>store_switch_times(models[, eps])</code>	Store event switching time in a sorted Numpy array in <code>System.switch_times</code> and an Ordered-Dict <code>System.switch_dict</code> .
<code>summary()</code>	Print out system summary.

continues on next page

Table 5 – continued from previous page

<code>supported_models([export])</code>	Return the support group names and model names in a table.
<code>switch_action(models)</code>	Invoke the actions associated with switch times.
<code>to_ipysheet(model[, vin])</code>	Return an ipysheet object for editing in Jupyter Notebook.
<code>undill()</code>	Deserialize the function calls from <code>~/.andes/calls.pkl</code> with <code>dill</code> .
<code>vars_to_dae(model)</code>	Copy variables values from models to <i>System.dae</i> .
<code>vars_to_models()</code>	Copy variable values from <i>System.dae</i> to models.

## System.add

`System.add(model, param_dict=None, **kwargs)`

Add a device instance for an existing model.

This methods calls the add method of *model* and registers the device *idx* to group.

## System.as\_dict

`System.as_dict(vin=False, skip_empty=True)`

Return system data as a dict where the keys are model names and values are dicts. Each dict has parameter names as keys and corresponding data in an array as values.

### Returns

**OrderedDict**

## System.calc\_pu\_coeff

`System.calc_pu_coeff()`

Perform per unit value conversion.

This function calculates the per unit conversion factors, stores input parameters to *vin*, and perform the conversion.

## System.call\_models

`System.call_models(method: str, models: collections.OrderedDict, *args, **kwargs)`  
Call methods on the given models.

### Parameters

**method** [str] Name of the model method to be called

**models** [OrderedDict, list, str] Models on which the method will be called

**args** Positional arguments to be passed to the model method

**kwargs** Keyword arguments to be passed to the model method

### Returns

The return value of the models in an `OrderedDict`

## System.collect\_ref

`System.collect_ref()`  
Collect indices into *BackRef* for all models.

## System.connectivity

`System.connectivity(info=True)`  
Perform connectivity check for system.

### Parameters

**info** [bool] True to log connectivity summary.

## System.dill

`System.dill()`  
Serialize generated numerical functions in `System.calls` with package `dill`.  
The serialized file will be stored to `~/ .andes/calls.pkl`, where `~` is the home directory path.

### Notes

This function sets `dill.settings['recurse'] = True` to serialize the function calls recursively.

### System.e\_clear

**System.e\_clear**(models: *collections.OrderedDict*)

Clear equation arrays in DAE and model variables.

This step must be called before calling *f\_update* or *g\_update* to flush existing values.

### System.f\_update

**System.f\_update**(models: *collections.OrderedDict*)

Call the differential equation update method for models in sequence.

### Notes

Updated equation values remain in models and have not been collected into DAE at the end of this step.

### System.fg\_to\_dae

**System.fg\_to\_dae**()

Collect equation values into the DAE arrays.

Additionally, the function resets the differential equations associated with variables pegged by anti-windup limiters.

### System.find\_devices

**System.find\_devices**()

Add dependent devices for all model based on *DeviceFinder*.

### System.find\_models

**System.find\_models**(flag: *Optional[Union[str, Tuple]]*, skip\_zero: *bool = True*)

Find models with at least one of the flags as True.

#### Parameters

**flag** [list, str] Flags to find

**skip\_zero** [bool] Skip models with zero devices

#### Returns

**OrderedDict** model name : model instance

**Warning:** Checking the number of devices has been centralized into this function. `models` passed to most System calls must be retrieved from here.

### System.fix\_address

#### System.fix\_address()

Fixes addressing issues after loading a snapshot.

This function properly sets `v` and `e` of internal variables as views of the corresponding DAE arrays.

Inputs will be refreshed for each model.

### System.from\_ipysheet

#### System.from\_ipysheet(*model: str, sheet, vin: bool = False*)

Set an ipysheet object back to model.

### System.g\_islands

#### System.g\_islands()

Reset algebraic mismatches for islanded buses.

### System.g\_update

#### System.g\_update(*models: collections.OrderedDict*)

Call the algebraic equation update method for models in sequence.

### Notes

Like *f\_update*, updated values have not collected into DAE at the end of the step.

### System.get\_config

#### System.get\_config()

Collect config data from models.

#### Returns

**dict** a dict containing the config from devices; class names are keys and configs in a dict are values.

## System.get\_z

`System.get_z(models: collections.OrderedDict)`

Get all discrete status flags in a numpy array. Values are written to `dae.z` in place.

### Returns

`numpy.array`

## System.import\_groups

`System.import_groups()`

Import all groups classes defined in `devices/group.py`.

Groups will be stored as instances with the name as class names. All groups will be stored to dictionary `System.groups`.

## System.import\_models

`System.import_models()`

Import and instantiate models as `System` member attributes.

Models defined in `models/__init__.py` will be instantiated *sequentially* as attributes with the same name as the class name. In addition, all models will be stored in dictionary `System.models` with model names as keys and the corresponding instances as values.

### Examples

`system.Bus` stores the *Bus* object, and `system.GENCLS` stores the classical generator object, `system.models['Bus']` points the same instance as `system.Bus`.

## System.import\_routines

`System.import_routines()`

Import routines as defined in `routines/__init__.py`.

Routines will be stored as instances with the name as class names. All groups will be stored to dictionary `System.groups`.

## Examples

`System.PFlow` is the power flow routine instance, and `System.TDS` and `System.EIG` are time-domain analysis and eigenvalue analysis routines, respectively.

## System.init

`System.init(models: collections.OrderedDict, routine: str)`

Initialize the variables for each of the specified models.

For each model, the initialization procedure is:

- Get values for all *ExtService*.
- Call the model *init()* method, which initializes internal variables.
- Copy variables to DAE and then back to the model.

## System.j\_islands

`System.j_islands()`

Set gy diagonals to eps for *a* and *v* variables of islanded buses.

## System.j\_update

`System.j_update(models: collections.OrderedDict, info=None)`

Call the Jacobian update method for models in sequence.

The procedure is - Restore the sparsity pattern with `andes.variables.dae.DAE.restore_sparse()` - For each sparse matrix in (fx, fy, gx, gy), evaluate the Jacobian function calls and add values.

## Notes

Updated Jacobians are immediately reflected in the DAE sparse matrices (fx, fy, gx, gy).

## System.l\_update\_eq

`System.l_update_eq(models: collections.OrderedDict, init=False)`

Update equation-dependent limiter discrete components by calling `l_check_eq` of models. Force set equations after evaluating equations.

This function is must be called after differential equation updates.

### System.l\_update\_var

**System.l\_update\_var**(*models: collections.OrderedDict, niter=None, err=None*)

Update variable-based limiter discrete states by calling `l_update_var` of models.

This function is must be called before any equation evaluation.

### System.link\_ext\_param

**System.link\_ext\_param**(*model=None*)

Retrieve values for ExtParam for the given models.

### System.load\_config

**static System.load\_config**(*conf\_path=None*)

Load config from an rc-formatted file.

#### Parameters

**conf\_path** [None or str] Path to the config file. If is *None*, the function body will not run.

#### Returns

**configparse.ConfigParser**

### System.precompile

**System.precompile**(*models: Optional[collections.OrderedDict] = None, nomp: bool = False, ncpu: int = 1*)

Trigger precompilation for the given models.

Arguments are the same as `prepare`.

### System.prepare

**System.prepare**(*quick=False, incremental=False, models=None, nomp=False, ncpu=1*)

Generate numerical functions from symbolically defined models.

All procedures in this function must be independent of test case.

#### Parameters

**quick** [bool, optional] True to skip pretty-print generation to reduce code generation time.

**incremental** [bool, optional] True to generate only for modified models, incrementally.

**models** [list, OrderedDict, None] List or OrderedDict of models to prepare

**nomp** [bool] True to disable multiprocessing

**Warning:** Generated lambda functions will be serialized to file, but pretty prints (SymPy objects) can only exist in the System instance on which prepare is called.

## Notes

Option `incremental` compares the md5 checksum of all var and service strings, and only re-generate for updated models.

## Examples

If one needs to print out LaTeX-formatted equations in a Jupyter Notebook, one need to generate such equations with

```
import andes
sys = andes.prepare()
```

Alternatively, one can explicitly create a System and generate the code

```
import andes
sys = andes.System()
sys.prepare()
```

## System.reload

`System.reload(case, **kwargs)`

Reload a new case in the same System object.

## System.remove\_pycapsule

`System.remove_pycapsule()`

Remove PyCapsule objects in solvers.

## System.reset

`System.reset(force=False)`

Reset to the state after reading data and setup (before power flow).

**Warning:** If TDS is initialized, reset will lead to unpredictable state.

## System.s\_update\_post

`System.s_update_post(models: collections.OrderedDict)`

Update variable services by calling `s_update_post` of models.

This function is called at the end of `System.init()`.

## System.s\_update\_var

`System.s_update_var(models: collections.OrderedDict)`

Update variable services by calling `s_update_var` of models.

This function is must be called before any equation evaluation after limiter update function `l_update_var`.

## System.save\_config

`System.save_config(file_path=None, overwrite=False)`

Save all system, model, and routine configurations to an rc-formatted file.

### Parameters

**file\_path** [str, optional] path to the configuration file default to `~/andes/andes.rc`.

**overwrite** [bool, optional] If file exists, True to overwrite without confirmation. Otherwise prompt for confirmation.

**Warning:** Saved config is loaded back and populated *at system instance creation time*. Configs from the config file takes precedence over default config values.

### System.set\_address

`System.set_address(models)`  
Set addresses for differential and algebraic variables.

### System.set\_config

`System.set_config(config=None)`  
Set configuration for the System object.  
Config for models are routines are passed directly to their constructors.

### System.set\_dae\_names

`System.set_dae_names(models)`  
Set variable names for differential and algebraic variables, right-hand side of external equations, and discrete flags.

### System.set\_var\_arrays

`System.set_var_arrays(models, inplace=True, alloc=True)`  
Set arrays (*v* and *e*) for internal variables to access dae arrays in place.  
This function needs to be called after de-serializing a System object, where the internal variables are incorrectly assigned new memory.

#### Parameters

**models** [OrderedDict, list, Model, optional] Models to execute.  
**inplace** [bool] True to retrieve arrays that share memory with dae  
**alloc** [bool] True to allocate for arrays internally

### System.setup

`System.setup()`  
Set up system for studies.  
This function is to be called after adding all device data.

## System.store\_adder\_setter

**System.store\_adder\_setter**(*models*)

Store non-inplace adders and setters for variables and equations.

## System.store\_existing

**System.store\_existing**()

Store existing models in *System.existing*.

TODO: Models with *TimerParam* will need to be stored anyway. This will allow adding switches on the fly.

## System.store\_no\_check\_init

**System.store\_no\_check\_init**(*models*)

Store differential variables with `check_init == False`.

## System.store\_sparse\_pattern

**System.store\_sparse\_pattern**(*models*: *collections.OrderedDict*)

Collect and store the sparsity pattern of Jacobian matrices.

This is a runtime function specific to cases.

## Notes

For gy matrix, always make sure the diagonal is reserved. It is a safeguard if the modeling user omitted the diagonal term in the equations.

## System.store\_switch\_times

**System.store\_switch\_times**(*models*, *eps*=0.0001)

Store event switching time in a sorted Numpy array in *System.switch\_times* and an *OrderedDict* *System.switch\_dict*.

*System.switch\_dict* has keys as event times and values as the *OrderedDict* of model names and instances associated with the event.

### Parameters

**models** [*OrderedDict*] model name : model instance

**eps** [float] The small time step size to use immediately before and after the event

### Returns

**array-like** self.switch\_times

### System.summary

**System.summary()**

Print out system summary.

### System.supported\_models

**System.supported\_models**(*export='plain'*)

Return the support group names and model names in a table.

#### Returns

**str** A table-formatted string for the groups and models

### System.switch\_action

**System.switch\_action**(*models: collections.OrderedDict*)

Invoke the actions associated with switch times.

Switch actions will be disabled if *flat=True* is passed to system.

### System.to\_ipysheet

**System.to\_ipysheet**(*model: str, vin: bool = False*)

Return an ipysheet object for editing in Jupyter Notebook.

### System.undill

**System.undill()**

Deserialize the function calls from `~/ .andes/calls.pkl` with dill.

If no change is made to models, future calls to `prepare()` can be replaced with `undill()` for acceleration.

### System.vars\_to\_dae

**System.vars\_to\_dae**(*model*)

Copy variables values from models to *System.dae*.

This function clears *DAE.x* and *DAE.y* and collects values from models.

**System.vars\_to\_models**

`System.vars_to_models()`  
Copy variable values from *System.dae* to models.

**5.1.2 andes.variables**

**Modules**

<code>andes.variables.dae</code>
<code>andes.variables.fileman</code>
<code>andes.variables.report</code>

**5.2 Routines**

<code>andes.routines</code>
-----------------------------

**5.2.1 andes.routines**

**Modules**

<code>andes.routines.base</code>	
<code>andes.routines.daeint</code>	Integration methods for DAE.
<code>andes.routines.eig</code>	Module for eigenvalue analysis.
<code>andes.routines.pflow</code>	Module for power flow calculation.
<code>andes.routines.tds</code>	ANDES module for time-domain simulation.

## andes.routines.base

### Classes

---

<i>BaseRoutine</i> ([system, config])	Base routine class.
---------------------------------------	---------------------

---

## andes.routines.base.BaseRoutine

**class** andes.routines.base.**BaseRoutine**(*system=None, config=None*)

Base routine class.

Provides references to system, config, and solver.

**\_\_init\_\_**(*system=None, config=None*)

### Methods

<i>doc</i> ([max_width, export])	Routine documentation interface.
<i>init</i> ()	Routine initialization interface.
<i>report</i> (**kwargs)	Report interface.
<i>run</i> (**kwargs)	Routine main entry point.
<i>summary</i> (**kwargs)	Summary interface

### BaseRoutine.doc

**BaseRoutine.doc**(*max\_width=78, export='plain'*)

Routine documentation interface.

### BaseRoutine.init

**BaseRoutine.init**()

Routine initialization interface.

### BaseRoutine.report

**BaseRoutine.report**(\*\*kwargs)

Report interface.

**BaseRoutine.run**

`BaseRoutine.run(**kwargs)`  
 Routine main entry point.

**BaseRoutine.summary**

`BaseRoutine.summary(**kwargs)`  
 Summary interface

**Attributes**

---

*class\_name*

---

**BaseRoutine.class\_name**

**property** `BaseRoutine.class_name`

**andes.routines.daeint**

Integration methods for DAE.

**Classes**

<i>BackEuler()</i>	Backward Euler's integration method.
<i>ImplicitIter()</i>	Base class for implicit iterative methods.
<i>Trapezoid()</i>	Trapezoidal methods.

**andes.routines.daeint.BackEuler**

**class** `andes.routines.daeint.BackEuler`  
 Backward Euler's integration method.  
**\_\_init\_\_**(\*args, \*\*kwargs)

## Methods

<code>calc_jac(tds, gxs, gys)</code>	Build full Jacobian matrix Ac for Trapezoid method.
<code>calc_q(x, f, Tf, h, x0, f0)</code>	Calculate the residual of algebraized differential equations.
<code>step(tds)</code>	Integrate with Implicit Trapezoidal Method (ITM) to the current time.

### BackEuler.calc\_jac

**static** BackEuler.**calc\_jac**(*tds, gxs, gys*)  
Build full Jacobian matrix Ac for Trapezoid method.

### BackEuler.calc\_q

**static** BackEuler.**calc\_q**(*x, f, Tf, h, x0, f0*)  
Calculate the residual of algebraized differential equations.

## Notes

Numba jit somehow slows down this function for the 14-bus and the 2k-bus systems.

### BackEuler.step

**static** BackEuler.**step**(*tds*)  
Integrate with Implicit Trapezoidal Method (ITM) to the current time.

This function has an internal Newton-Raphson loop for algebraized semi-explicit DAE. The function returns the convergence status when done but does NOT progress simulation time.

## Returns

**bool** Convergence status in `tds.converged`.

### andes.routines.daeint.ImplicitIter

**class** andes.routines.daeint.**ImplicitIter**  
Base class for implicit iterative methods.  
**\_\_init\_\_**(*\*args, \*\*kwargs*)

## Methods

---

`calc_jac(tds, gxs, gys)`

---

`calc_q(x, f, Tf, h, x0, f0)`

---

<code>step(tds)</code>	Integrate with Implicit Trapezoidal Method (ITM) to the current time.
------------------------	---

---

### ImplicitIter.calc\_jac

```
static ImplicitIter.calc_jac(tds, gxs, gys)
```

### ImplicitIter.calc\_q

```
static ImplicitIter.calc_q(x, f, Tf, h, x0, f0)
```

### ImplicitIter.step

```
static ImplicitIter.step(tds)
```

Integrate with Implicit Trapezoidal Method (ITM) to the current time.

This function has an internal Newton-Raphson loop for algebraized semi-explicit DAE. The function returns the convergence status when done but does NOT progress simulation time.

#### Returns

**bool** Convergence status in `tds.converged`.

## andes.routines.daeint.Trapezoid

```
class andes.routines.daeint.Trapezoid
```

Trapezoidal methods.

```
    __init__(*args, **kwargs)
```

## Methods

<code>calc_jac</code> (tds, gxs, gys)	Build full Jacobian matrix Ac for Trapezoid method.
<code>calc_q</code> (x, f, Tf, h, x0, f0)	Calculate the residual of algebraized differential equations.
<code>step</code> (tds)	Integrate with Implicit Trapezoidal Method (ITM) to the current time.

### Trapezoid.calc\_jac

**static** Trapezoid.**calc\_jac**(tds, gxs, gys)  
Build full Jacobian matrix Ac for Trapezoid method.

### Trapezoid.calc\_q

**static** Trapezoid.**calc\_q**(x, f, Tf, h, x0, f0)  
Calculate the residual of algebraized differential equations.

## Notes

Numba jit somehow slows down this function for the 14-bus and the 2k-bus systems.

### Trapezoid.step

**static** Trapezoid.**step**(tds)  
Integrate with Implicit Trapezoidal Method (ITM) to the current time.

This function has an internal Newton-Raphson loop for algebraized semi-explicit DAE. The function returns the convergence status when done but does NOT progress simulation time.

## Returns

**bool** Convergence status in tds.converged.

## andes.routines.eig

Module for eigenvalue analysis.

## Classes

<i>EIG</i> (system, config)	Eigenvalue analysis routine
-----------------------------	-----------------------------

### andes.routines.eig.EIG

**class** andes.routines.eig.**EIG**(system, config)

Eigenvalue analysis routine

**\_\_init\_\_**(system, config)

#### Methods

<i>calc_As</i> ([dense])	Return state matrix and store to <code>self.As</code> .
<i>calc_eig</i> ([As])	Calculate eigenvalues and right eigen vectors.
<i>calc_pfactor</i> ([As])	Compute participation factor of states in eigenvalues.
<i>doc</i> ([max_width, export])	Routine documentation interface.
<i>export_mat</i> ()	Export state matrix to a <CaseName>_As.mat file with the variable name As, where <CaseName> is the test case name.
<i>find_zero_states</i> ()	Find the indices of states associated with zero time constants in <code>x</code> .
<i>init</i> ()	Routine initialization interface.
<i>plot</i> ([mu, fig, ax, left, right, ymin, ymax, ...])	Plot utility for eigenvalues in the S domain.
<i>post_process</i> ()	Post processing of eigenvalues.
<i>report</i> ([x_name])	Save eigenvalue analysis reports.
<i>run</i> (**kwargs)	Run small-signal stability analysis.
<i>summary</i> ()	Print out a summary to <code>logger.info</code> .

### EIG.calc\_As

**EIG.calc\_As**(dense=True)

Return state matrix and store to `self.As`.

#### Returns

**kvxopt.matrix** state matrix

## Notes

For systems in the mass-matrix formulation,

$$\begin{aligned}T\dot{x} &= f(x, y) \\ 0 &= g(x, y)\end{aligned}$$

Assume  $T$  is non-singular, the state matrix is calculated from

$$A_s = T^{-1}(f_x - f_y * g_y^{-1} * g_x)$$

## EIG.calc\_eig

**EIG.calc\_eig**(*As=None*)

Calculate eigenvalues and right eigen vectors.

This function is a wrapper to `np.linalg.eig`. Results are returned but not stored to EIG.

### Returns

**np.array(dtype=complex)** eigenvalues

**np.array()** right eigenvectors

## EIG.calc\_pfactor

**EIG.calc\_pfactor**(*As=None*)

Compute participation factor of states in eigenvalues.

Each row in the participation factor correspond to one state, and each column correspond to one mode.

### Parameters

**As** [np.array or None] State matrix to process. If None, use `self.As`.

### Returns

**np.array(dtype=complex)** eigenvalues

**np.array** participation factor matrix

## EIG.doc

**EIG.doc**(*max\_width=78, export='plain'*)

Routine documentation interface.

## EIG.export\_mat

### EIG.export\_mat()

Export state matrix to a <CaseName>\_As.mat file with the variable name As, where <CaseName> is the test case name.

State variable names are stored in variables `x_name` and `x_tex_name`.

#### Returns

**bool** True if successful

## EIG.find\_zero\_states

### EIG.find\_zero\_states()

Find the indices of states associated with zero time constants in `x`.

## EIG.init

### EIG.init()

Routine initialization interface.

## EIG.plot

**EIG.plot** (*mu=None, fig=None, ax=None, left=-6, right=0.5, ymin=-8, ymax=8, damping=0.05, line\_width=0.5, dpi=100, figsize=None, base\_color='black', show=True, latex=True*)

Plot utility for eigenvalues in the S domain.

#### Parameters

**mu** [array, optional] an array of complex eigenvalues

**fig** [figure handl, optional] existing matplotlib figure handle

**ax** [axis handle, optional] existing axis handle

**left** [int, optional] left tick for the x-axis, by default -6

**right** [float, optional] right tick, by default 0.5

**ymin** [int, optional] bottom tick, by default -8

**ymax** [int, optional] top tick, by default 8

**damping** [float, optional] damping value for which the dash plots are drawn

**line\_width** [float, optional] default line width, by default 0.5

**dpi** [int, optional] figure dpi, by default 100

**figsize** [[type], optional] default figure size, by default None

**base\_color** [str, optional] base color for negative eigenvalues

**show** [bool, optional] True to show figure after plot, by default True

**latex** [bool, optional] True to use latex, by default True

#### Returns

**figure** matplotlib figure object

**axis** matplotlib axis object

### EIG.post\_process

**EIG.post\_process()**

Post processing of eigenvalues.

### EIG.report

**EIG.report**(*x\_name=None, \*\*kwargs*)

Save eigenvalue analysis reports.

#### Returns

None

### EIG.run

**EIG.run**(*\*\*kwargs*)

Run small-signal stability analysis.

### EIG.summary

**EIG.summary()**

Print out a summary to `logger.info`.

### Attributes

---

*class\_name*

---

**EIG.class\_name**

**property** EIG.class\_name

## andes.routines.pflow

Module for power flow calculation.

### Classes

<i>PFlow</i> ([system, config])	Power flow calculation routine.
---------------------------------	---------------------------------

## andes.routines.pflow.PFlow

**class** andes.routines.pflow.PFlow(*system=None, config=None*)

Power flow calculation routine.

**\_\_init\_\_**(*system=None, config=None*)

### Methods

<i>doc</i> ([max_width, export])	Routine documentation interface.
<i>init</i> ()	Initialize variables for power flow.
<i>newton_krylov</i> ([verbose])	Full Newton-Krylov method from SciPy.
<i>nr_step</i> ()	Single step using Newton-Raphson method.
<i>report</i> ()	Write power flow report to text file.
<i>run</i> (**kwargs)	Full Newton-Raphson method.
<i>summary</i> ()	Output a summary for the PFlow routine.

### PFlow.doc

PFlow.doc(*max\_width=78, export='plain'*)

Routine documentation interface.

### **PFlow.init**

**PFlow.init()**

Initialize variables for power flow.

### **PFlow.newton\_krylov**

**PFlow.newton\_krylov**(*verbose=False*)

Full Newton-Krylov method from SciPy.

#### **Parameters**

**verbose** True if verbose.

#### **Returns**

**np.array** Solutions *dae.xy*.

**Warning:** The result might be wrong if discrete are in use!

### **PFlow.nr\_step**

**PFlow.nr\_step()**

Single step using Newton-Raphson method.

#### **Returns**

**float** maximum absolute mismatch

### **PFlow.report**

**PFlow.report()**

Write power flow report to text file.

### **PFlow.run**

**PFlow.run**(*\*\*kwargs*)

Full Newton-Raphson method.

#### **Returns**

**bool** convergence status

**PFlow.summary**

`PFlow.summary()`  
Output a summary for the PFlow routine.

**Attributes**

---

<i>class_name</i>
-------------------

---

**PFlow.class\_name**

`property PFlow.class_name`

**andes.routines.tds**

ANDES module for time-domain simulation.

**Classes**

---

<i>TDS</i> ([system, config])	Time-domain simulation routine.
-------------------------------	---------------------------------

---

**andes.routines.tds.TDS**

**class** `andes.routines.tds.TDS(system=None, config=None)`  
Time-domain simulation routine.

Some cases may be sensitive to large convergence tolerance `config.tol`. If numerical oscillation happens, try reducing `config.tol` to `1e-6`.

`__init__`(system=None, config=None)

**Methods**

---

<i>calc_h</i> ([resume])	Calculate the time step size during the TDS.
<i>do_switch</i> ()	Checks if is an event time and perform switch if true.
<i>doc</i> ([max_width, export])	Routine documentation interface.
<i>fg_update</i> (models[, init])	Perform one round of evaluation for one iteration step.

---

continues on next page

Table 23 – continued from previous page

<code>init()</code>	Initialize the status, storage and values for TDS.
<code>itm_step()</code>	Integrate for the step size of <code>self.h</code> using implicit trapezoid method.
<code>load_plotter()</code>	Manually load a plotter into <code>TDS.plotter</code> .
<code>report(**kwargs)</code>	Report interface.
<code>reset()</code>	Reset internal states to pre-init condition.
<code>rewind(t)</code>	TODO: rewind to a past time.
<code>run([no_summary])</code>	Run time-domain simulation using numerical integration.
<code>save_output([npz])</code>	Save the simulation data into two files: a <code>.lst</code> file and a <code>.npz</code> file.
<code>set_method([name])</code>	Set DAE solution method.
<code>streaming_init()</code>	Send out initialization variables and process init from modules.
<code>streaming_step()</code>	Sync, handle and streaming for each integration step.
<code>summary()</code>	Print out a summary of TDS options to logger.info.
<code>test_init()</code>	Update <code>f</code> and <code>g</code> to see if initialization is successful.

## TDS.calc\_h

`TDS.calc_h(resume=False)`

Calculate the time step size during the TDS.

### Parameters

**resume** [bool] If True, calculate the initial step size.

### Returns

**float** computed time step size stored in `self.h`

### Notes

A heuristic function is used for variable time step size

```

    min(0.50 * h, hmin), if niter >= 15
h = max(1.10 * h, hmax), if niter <= 6
    min(0.95 * h, hmin), otherwise

```

## TDS.do\_switch

### TDS.do\_switch()

Checks if is an event time and perform switch if true.

Time is approximated with a tolerance of 1e-8.

## TDS.doc

### TDS.doc(*max\_width=78, export='plain'*)

Routine documentation interface.

## TDS.fg\_update

### TDS.fg\_update(*models, init=False*)

Perform one round of evaluation for one iteration step. The following operations are performed in order:

- discrete flags updating through `l_update_var`
- variable service updating through `s_update_var`
- evaluation of the right-hand-side of `f`
- equation-dependent discrete flags updating through `l_update_eq`
- evaluation of the right-hand-side of `g`
- collection of residuals into `dae` through `fg_to_dae`.

## TDS.init

### TDS.init()

Initialize the status, storage and values for TDS.

#### Returns

**array-like** The initial values of `xy`.

## TDS.itm\_step

### TDS.itm\_step()

Integrate for the step size of `self.h` using implicit trapezoid method.

#### Returns

**bool** Convergence status in `self.converged`.

## **TDS.load\_plotter**

**TDS.load\_plotter()**

Manually load a plotter into `TDS.plotter`.

## **TDS.report**

**TDS.report(\*\*kwargs)**

Report interface.

## **TDS.reset**

**TDS.reset()**

Reset internal states to pre-init condition.

## **TDS.rewind**

**TDS.rewind(*t*)**

TODO: rewind to a past time.

## **TDS.run**

**TDS.run(*no\_summary=False*, \*\*kwargs)**

Run time-domain simulation using numerical integration.

The default method is the Implicit Trapezoidal Method (ITM).

## **TDS.save\_output**

**TDS.save\_output(*npz=True*)**

Save the simulation data into two files: a *.lst* file and a *.npz* file.

This function saves the output regardless of the *files.no\_output* flag.

### **Parameters**

**npz** [bool] True to save in npz format; False to save in npy format.

### **Returns**

-----

**bool** True if files are written. False otherwise.

### TDS.set\_method

**TDS.set\_method**(*name*: *str* = 'trapezoid')

Set DAE solution method.

**name** [str, optional, default: trapezoid] DAE solver name

### TDS.streaming\_init

**TDS.streaming\_init**()

Send out initialization variables and process init from modules.

**Returns**

None

### TDS.streaming\_step

**TDS.streaming\_step**()

Sync, handle and streaming for each integration step.

**Returns**

None

### TDS.summary

**TDS.summary**()

Print out a summary of TDS options to logger.info.

**Returns**

None

### TDS.test\_init

**TDS.test\_init**()

Update f and g to see if initialization is successful.

## Attributes

---

*class\_name*

---

**TDS.class\_name****property** TDS.class\_name

## 5.3 Plot

---

*andes.plot*

---

The Andes plotting tool.

---

### 5.3.1 andes.plot

The Andes plotting tool.

## Functions

---

*eig\_plot*(name, args)

---

---

*isfloat*(value)

---

---

*isint*(value)

---

---

*label\_latexify*(label)

---

Convert a label to latex format by appending surrounding \$ and escaping spaces

---

*parse\_y*(y, upper[, lower])

---

Parse command-line input for Y indices and return a list of indices

---

*scale\_func*(k)

---

Return a lambda function that scales its input by k

---

*tdsplot*(filename, y[, x, to\_csv, find, ...])

---

TDS plot main function based on the new TDSDData class.

---

**eig\_plot**

`andes.plot.eig_plot(name, args)`

**isfloat**

`andes.plot.isfloat(value)`

**isint**

`andes.plot.isint(value)`

**label\_latexify**

`andes.plot.label_latexify(label)`

Convert a label to latex format by appending surrounding \$ and escaping spaces

**Parameters**

**label** [str] The label string to be converted to latex expression

**Returns**

**str** A string with \$ surrounding

**parse\_y**

`andes.plot.parse_y(y, upper, lower=0)`

Parse command-line input for Y indices and return a list of indices

**Parameters**

**y** [Union[List, Set, Tuple]]

**Input for Y indices. Could be single item (with or without colon), or multiple items**

**upper** [int] Upper limit. In the return list y,  $y[i] \leq upper$ .

**lower** [int] Lower limit. In the return list y,  $y[i] \geq lower$ .

**Returns**

## scale\_func

`andes.plot.scale_func(k)`

Return a lambda function that scales its input by k

### Parameters

**k** [float] The scaling factor of the returned lambda function

### Returns

-----

**Lambda function**

## tdsplot

`andes.plot.tdsplot(filename, y, x=(0,), to_csv=False, find=None, xargs=None, exclude=None, **kwargs)`

TDS plot main function based on the new TDSDData class.

### Parameters

**filename** [str] Path to the ANDES TDS output data file. Works without extension.

**x** [list or int, optional] The index for the x-axis variable. x=0 by default for time

**y** [list or int] The indices for the y-axis variable

**to\_csv** [bool] True if need to export to a csv file

**find** [str, optional] if not none, specify the variable name to find

**xargs** [str, optional] similar to find, but return the result indices with file name, x idx name for xargs

**exclude** [str, optional] variable name pattern to exclude

### Returns

**TDSDData object**

## Classes

---

*TDSDData*([full\_name, mode, dae, path])

A data container for loading and plotting results from Andes time-domain simulation.

---

**andes.plot.TSDData**

**class** andes.plot.TSDData(full\_name=None, mode='file', dae=None, path=None)

A data container for loading and plotting results from Andes time-domain simulation.

**\_\_init\_\_**(full\_name=None, mode='file', dae=None, path=None)

**Methods**

<i>bqplot_data</i> (xdata, ydata, *, xheader, ...)	Plot with bqplot.
<i>data_to_df</i> ()	Convert to pandas.DataFrame
<i>export_csv</i> ([path, idx, header, formatted, ...])	Export to a csv file.
<i>find</i> (query[, exclude, formatted, idx_only])	Return variable names and indices matching <i>query</i> .
<i>get_call</i> ([backend])	Get the internal <i>plot_data</i> function for the specified backend.
<i>get_header</i> (idx[, formatted])	Return a list of the variable names at the given indices.
<i>get_values</i> (idx)	Return the variable values at the given indices.
<i>guess_event_time</i> ()	Guess the event starting time from the input data by checking when the values start to change
<i>load_dae</i> ()	Load from DAE time series
<i>load_lst</i> ()	Load the lst file into internal data structures <i>_idx</i> , <i>_fname</i> , <i>_uname</i> , and counts the number of variables to <i>nvars</i> .
<i>load_npy_or_csv</i> ([delimiter])	Load the npy, zpy or (the legacy) csv file into the internal data structure <i>self._xy</i> .
<i>panoview</i> (mdl, *, ncols, vars, idx, a, figsize)	Panoramic view of variables of a given model instance.
<i>plot</i> (yidx[, xidx, a, ytimes, ycalc, left, ...])	Entry function for plotting.
<i>plot_data</i> (xdata, ydata, *, xheader, ...)	Plot lines for the supplied data and options.
<i>plotn</i> (nrows, ncols, yidxes[, xidxes, dpi, ...])	Plot multiple subfigures in one figure.

**TSDData.bqplot\_data**

TSDData.**bqplot\_data**(xdata, ydata, \*, xheader=None, yheader=None, xlabel=None, ylabel=None, left=None, right=None, ymin=None, ymax=None, legend=True, grid=False, fig=None, dpi=100, line\_width=1.0, greyscale=False, savefig=None, save\_format=None, title=None, \*\*kwargs)

Plot with bqplot. Experimental and incomplete.

### **TDSData.data\_to\_df**

**TDSData.data\_to\_df()**

Convert to pandas.DataFrame

### **TDSData.export\_csv**

**TDSData.export\_csv**(*path=None, idx=None, header=None, formatted=False, sort\_idx=True, fmt='%%.18e'*)

Export to a csv file.

#### **Parameters**

**path** [str] path of the csv file to save

**idx** [None or array-like, optional] the indices of the variables to export. Export all by default

**header** [None or array-like, optional] customized header if not *None*. Use the names from the 1st file by default

**formatted** [bool, optional] Use LaTeX-formatted header. Does not apply when using customized header

**sort\_idx** [bool, optional] Sort by idx or not, # TODO: implement sort

**fmt** [str] cell formatter

### **TDSData.find**

**TDSData.find**(*query, exclude=None, formatted=False, idx\_only=False*)

Return variable names and indices matching *query*.

#### **Parameters**

**query** [str] The string for querying variables. Multiple conditions can be separated by comma without space.

**exclude** [str, optional] A string pattern to be excluded

**formatted** [bool, optional] True to return formatted names, False otherwise

**idx\_only** [bool, optional] True if only return indices

#### **Returns**

(**list**, **list**) (List of found indices, list of found names)

**TDSData.get\_call****TDSData.get\_call**(*backend=None*)Get the internal *plot\_data* function for the specified backend.**TDSData.get\_header****TDSData.get\_header**(*idx, formatted=False*)

Return a list of the variable names at the given indices.

**Parameters****idx** [list or int] The indices of the variables to retrieve**formatted** [bool] True to retrieve latex-formatted names, False for unformatted names**Returns****list** A list of variable names (headers)**TDSData.get\_values****TDSData.get\_values**(*idx*)

Return the variable values at the given indices.

**Parameters****idx** [list] The index of the variables to retrieve. *idx=0* is for Time. Variable indices start at 1.**Returns****np.ndarray** Variable data**TDSData.guess\_event\_time****TDSData.guess\_event\_time**()

Guess the event starting time from the input data by checking when the values start to change

**TDSDData.load\_dae****TDSDData.load\_dae()**

Load from DAE time series

**TDSDData.load\_lst****TDSDData.load\_lst()**Load the lst file into internal data structures *\_idx*, *\_fname*, *\_uname*, and counts the number of variables to *nvars*.**Returns**

None

**TDSDData.load\_npy\_or\_csv****TDSDData.load\_npy\_or\_csv(*delimiter*='')**Load the npy, zpy or (the legacy) csv file into the internal data structure *self.\_xy*.**Parameters****delimiter** [str, optional] The delimiter for the case file. Default to comma.**Returns**

None

**TDSDData.panoview****TDSDData.panoview(*mdl*, \*, *ncols*=3, *vars*=None, *idx*=None, *a*=None, *figsize*=None, *\*\*kwargs*)**

Panoramic view of variables of a given model instance.

Select variables through *vars*. Select devices through *idx* or *a*, which has a higher priority.This function also takes other arguments recognizable by *self.plot*.**Parameters****mdl** [ModelBase] Model instance**ncol** [int] Number of columns**var** [list of str] A list of variable names to display**idx** [list] A list of device *idx*-es for showing**a** [list of int] A list of device 0-based positions for showing**figsize** [tuple] Figure size for plotting

## Examples

To plot omega and delta of GENROUs GENROU\_1 and GENROU\_2:

```
system.TDS.plt.plot(system.GENROU,
                    vars=['omega', 'delta'],
                    idx=['GENROU_1', 'GENROU_2'])
```

## TDSData.plot

**TDSData.plot**(yidx, xidx=(0,), \*, a=None, ytimes=None, ycalc=None, left=None, right=None, ymin=None, ymax=None, xlabel=None, ylabel=None, xheader=None, yheader=None, legend=None, grid=False, greyscale=False, latex=True, dpi=100, line\_width=1.0, font\_size=12, savefig=None, save\_format=None, show=True, title=None, linestyle=None, use\_bqplot=False, hline1=None, hline2=None, vline1=None, vline2=None, hline=None, vline=None, fig=None, ax=None, backend=None, set\_xlim=True, set\_ylim=True, autoscale=False, legend\_bbox=None, legend\_loc=None, legend\_ncol=1, figsize=None, color=None, \*\*kwargs)

Entry function for plotting.

This function retrieves the x and y values based on the *xidx* and *yidx* inputs, applies scaling functions *ytimes* and *ycalc* sequentially, and delegates the plotting to the backend.

### Parameters

- yidx** [list or int] The indices for the y-axis variables
- xidx** [tuple or int, optional] The index for the x-axis variable
- a** [tuple or list, optional] The 0-indexed sub-indices into *yidx* to plot.
- ytimes** [float, optional] A scaling factor to apply to all y values.
- left** [float] The starting value of the x axis
- right** [float] The ending value of the x axis
- ymin** [float] The minimum value of the y axis
- ymax** [float] The maximum value of the y axis
- ylabel** [str] Text label for the y axis
- yheader** [list] A list containing the variable names for the y-axis variable
- title** [str] Title string to be shown at the top
- fig** Existing figure object to draw the axis on.
- ax** Existing axis object to draw the lines on.

### Returns

- (**fig**, **ax**) Figure and axis handles for matplotlib backend.

**fig** Figure object for bqplot backend.

#### Other Parameters

**yca1c:** callable, optional A callable to apply to all y values after scaling with *ytimes*.

**xlabel** [str] Text label for the x axis

**xheader** [list] A list containing the variable names for the x-axis variable

**legend** [bool] True to show legend and False otherwise

**legend\_ncol** [int] Number of columns in legend

**legend\_bbox** [tuple of two floats] legend box to anchor

**grid** [bool] True to show grid and False otherwise

**latex** [bool] True to enable latex and False to disable

**greyscale** [bool] True to use greyscale, False otherwise

**savefig** [bool or str] True to save to png figure file. str is treated as the output file name.

**save\_format** [str] File extension string (pdf, png or jpg) for the savefig format

**dpi** [int] Dots per inch for screen print or save. *savefig* uses a minimum of 200 dpi

**line\_width** [float] Plot line width

**font\_size** [float] Text font size (labels and legends)

**figsize** [tuple] Figure size passed when creating new figure

**show** [bool] True to show the image

**backend** [str or None] *bqplot* to use the bqplot backend in notebook. None for matplotlib.

**hline1:** float, optional Dashed horizontal line 1

**hline2:** float, optional Dashed horizontal line 2

**vline1:** float, optional Dashed horizontal line 1

**vline2:** float, optional Dashed vertical line 2

**hline:** float or Iterable y-axis location of horizontal line(s)

**vline:** float or Iterable x-axis location of vertical line(s)

## TDSData.plot\_data

```
TDSData.plot_data(xdata, ydata, *, xheader=None, yheader=None, xlabel=None, ylabel=None,
                  linestyle=None, left=None, right=None, ymin=None, ymax=None,
                  legend=None, grid=False, fig=None, ax=None, latex=True, dpi=100,
                  line_width=1.0, font_size=12, greyscale=False, savefig=None,
                  save_format=None, show=True, title=None, hline1=None, hline2=None,
                  vline1=None, hline=None, vline=None, vline2=None, set_xlim=True,
                  set_ylim=True, autoscale=False, figsize=None, legend_bbox=None,
                  legend_loc=None, legend_ncol=1, mask=True, color=None, **kwargs)
```

Plot lines for the supplied data and options.

This functions takes *xdata* and *ydata* values. If you provide variable indices instead of values, use *plot()*.

See the argument lists of *plot()* for more.

### Parameters

**xdata** [array-like] An array-like object containing the values for the x-axis variable

**ydata** [array] An array containing the values of each variables for the y-axis variable. The row of *ydata* must match the row of *xdata*. Each column correspondings to a variable.

**mask** [bool] If enabled (1), when specifying axis limits, only data in the limits will be used for plotting to optimize for autoscaling. It is done through an index mask.

### Returns

(**fig**, **ax**) The figure and axis handles

## Examples

To plot the results of arithmetic calculation of variables, retrieve the values, do the calculation, and plot with *plot\_data*.

```
>>> v = ss.dae.ts.y[:, ss.PVD1.v.a]
>>> Ipcmd = ss.dae.ts.y[:, ss.PVD1.Ipcmd_y.a]
>>> t = ss.dae.ts.t
```

```
>>> ss.TDS.plt.plot_data(t, v * Ipcmd,
>>>                      xlabel='Time [s]',
>>>                      ylabel='Ipcmd [pu]')
```

## TDSData.plotn

`TDSData.plotn(nrows: int, ncols: int, yidxes, xidxes=None, *, dpi=100, titles=None, a=None, figsize=None, xlabel=None, ylabel=None, sharex=None, sharey=None, show=True, xlabel_offs=(0.5, 0.01), ylabel_offs=(0.05, 0.5), hspace=0.2, wspace=0.2, **kwargs)`

Plot multiple subfigures in one figure.

Parameters `xidxes`, `a`, `xlabels` and `ylabels`, if provided, must have the same length as `yidxes`.

### Parameters

- nrows** [int] number of rows
- ncols** [int] number of cols
- yidx** A list of *BaseVar* or index lists.

## 5.4 I/O

---

*andes.io*

---

### 5.4.1 andes.io

#### Functions

<i>dump</i> (system, output_format[, full_path, ...])	Dump the System data into the requested output format.
<i>get_output_ext</i> (out_format)	
<i>guess</i> (system)	Guess the input format based on extension and content.
<i>parse</i> (system)	Parse input file with the given format in <i>system.files.input_format</i> .
<i>read_file_like</i> (infile)	Read a file-like object and return a list of splitted lines.

## dump

`andes.io.dump(system, output_format, full_path=None, overwrite=False, **kwargs)`

Dump the System data into the requested output format.

### Parameters

**system** System object

**output\_format** [str] Output format name. 'xlsx' will be used if is not an instance of *str*.

### Returns

**bool** True if successful; False otherwise.

## get\_output\_ext

`andes.io.get_output_ext(out_format)`

## guess

`andes.io.guess(system)`

Guess the input format based on extension and content.

Also stores the format name to *system.files.input\_format*.

### Parameters

**system** [System] System instance with the file name set to *system.files*

### Returns

**str** format name

## parse

`andes.io.parse(system)`

Parse input file with the given format in *system.files.input\_format*.

### Returns

**bool** True if successful; False otherwise.

## read\_file\_like

`andes.io.read_file_like(infile: Union[str, io.IOBase])`

Read a file-like object and return a list of splitted lines.

## Modules

---

<code>andes.io.em_psse</code>	PSSE RAW parser from em_psse
<code>andes.io.json</code>	JSON reader and writer for ANDES.
<code>andes.io.matpower</code>	Simple MATPOWER format parser
<code>andes.io.psse</code>	PSS/E file parser.
<code>andes.io.psse_new</code>	

---

<code>andes.io.streaming</code>	
---------------------------------	--

---

<code>andes.io.txt</code>	
---------------------------	--

---

<code>andes.io.xlsx</code>	Excel reader and writer for ANDES power system parameters
----------------------------	---

---

## andes.io.em\_psse

PSSE RAW parser from em\_psse

License Pending

## Functions

---

<code>get_signals(line_num, line, current_mode)</code>	
--	--

---

<code>parse_raw(in_file_name)</code>	This function will parse a RAW file and return a PyPSA model
--------------------------------------	--

---

<code>read_transformer(lines, records)</code>	
---	--

---

<code>read_twodc(lines, records)</code>	
---	--

---

## get\_signals

```
andes.io.em_psse.get_signals(line_num, line, current_mode)
```

## parse\_raw

```
andes.io.em_psse.parse_raw(in_file_name)
```

This function will parse a RAW file and return a PyPSA model

## read\_transformer

```
andes.io.em_psse.read_transformer(lines, records)
```

## read\_twodc

```
andes.io.em_psse.read_twodc(lines, records)
```

## andes.io.json

JSON reader and writer for ANDES.

## Functions

<code>read(system, infile)</code>	Read JSON file with ANDES model data into an empty system.
<code>testlines(infile)</code>	
<code>write(system, outfile[, skip_empty, overwrite])</code>	Write loaded ANDES system data into a JSON file.

## read

```
andes.io.json.read(system, infile: Union[str, io.IOBase])
```

Read JSON file with ANDES model data into an empty system.

### Parameters

**system** [System] Empty System instance

**infile** [str or io.BaseIO] str: path to the input file; or io.BaseIO: a stream to read from

### Returns

**System** System instance after succeeded

## testlines

`andes.io.json.testlines(infile)`

## write

`andes.io.json.write(system, outfile, skip_empty=True, overwrite=None, **kwargs)`

Write loaded ANDES system data into a JSON file.

### Parameters

**system** [System] A loaded system with parameters

**outfile** [str] Path to the output file

**skip\_empty** [bool] Skip output of empty models (n = 0)

**overwrite** [bool] None to prompt for overwrite selection; True to overwrite; False to not overwrite

### Returns

**bool** True if file written; False otherwise

## andes.io.matpower

Simple MATPOWER format parser

## Functions

---

<code>read(system, file)</code>	Read a MATPOWER data file into mpc, and build andes device elements.
<code>testlines(infile)</code>	Test if this file is in the MATPOWER format.

---

## read

`andes.io.matpower.read(system, file)`

Read a MATPOWER data file into mpc, and build andes device elements.

## testlines

`andes.io.matpower.testlines(infile)`

Test if this file is in the MATPOWER format.

NOT YET IMPLEMENTED.

## andes.io.psse

PSS/E file parser.

Include a RAW parser and a DYR parser.

## Functions

<code>get_block_lines(b, mdata)</code>	Return the number of lines based on the block index in the RAW file.
<code>read(system, file)</code>	Read PSS/E RAW file v32/v33 formats.
<code>read_add(system, file)</code>	Read an addition PSS/E dyr file.
<code>sort_psse_models(dyr_yaml, system)</code>	Sort supported models so that model names are ordered by dependency.
<code>testlines(infile)</code>	Check the raw file for frequency base.

## get\_block\_lines

`andes.io.psse.get_block_lines(b, mdata)`

Return the number of lines based on the block index in the RAW file.

## read

`andes.io.psse.read(system, file)`

Read PSS/E RAW file v32/v33 formats.

## read\_add

`andes.io.psse.read_add(system, file)`

Read an addition PSS/E dyr file.

### Parameters

**system** [System] System instance to which data will be loaded

**file** [str] Path to the additional *dyr* file

### Returns

**bool** data parsing status

## **sort\_psse\_models**

`andes.io.psse.sort_psse_models(dyr_yaml, system)`

Sort supported models so that model names are ordered by dependency.

Dependency is determined by checking the `find` key in `psse-dyr.yaml` for each model.

### **Returns**

**list** The sequence of model names for loading parameters.

## **testlines**

`andes.io.psse.testlines(infile)`

Check the raw file for frequency base.

## **andes.io.psse\_new**

### **Functions**

---

*is\_format*(*fid*)

Check the raw file for frequency base

---

*read*(*system*, *file\_name*)

---

## **is\_format**

`andes.io.psse_new.is_format(fid)`

Check the raw file for frequency base

**read**

`andes.io.psse_new.read(system, file_name)`

**andes.io.streaming****Classes**

---

<i>Streaming</i> (system)	ANDES data streaming class to interface with CURENT LTB.
---------------------------	--

---

**andes.io.streaming.Streaming**

**class** `andes.io.streaming.Streaming(system)`  
 ANDES data streaming class to interface with CURENT LTB.

**\_\_init\_\_**(system)

**Methods**

---

<i>build_init</i> ()	Build <i>Varheader</i> , <i>Idxvgs</i> and <i>SysParam</i> after power flow routine
<i>connect</i> ()	Connect to DiME 2 server.
<i>finalize</i> ()	Send DONE signal when simulation completes
<i>handle_alter</i> (Alter)	Handle parameter altering
<i>handle_event</i> (Event)	Handle Fault, Breaker, Syn and Load Events
<i>record_module_init</i> (name, init_var)	Record the variable requests from modules
<i>send_init</i> ([recepient])	Broadcast <i>Varheader</i> , <i>Idxvgs</i> and <i>SysParam</i> to all DiME clients after power flow routine
<i>sync_and_handle</i> ()	Sync until the queue is empty.
<i>transpose_matlab_row</i> (a)	
<i>vars_to_modules</i> ()	Stream the results from the last step to modules
<i>vars_to_pmu</i> ()	Broadcast all PMU measurements and BusFreq measurements in the variable <i>pmudata</i>

---

### **Streaming.build\_init**

**Streaming.build\_init()**

Build *Varheader*, *Idxvgs* and *SysParam* after power flow routine

### **Streaming.connect**

**Streaming.connect()**

Connect to DiME 2 server.

If *dime\_address* is specified from the command-line, streaming will be automatically enabled. Otherwise, settings from the Config file will be used.

### **Streaming.finalize**

**Streaming.finalize()**

Send DONE signal when simulation completes

**Returns** None

### **Streaming.handle\_alter**

**Streaming.handle\_alter(*Alter*)**

Handle parameter altering

### **Streaming.handle\_event**

**Streaming.handle\_event(*Event*)**

Handle Fault, Breaker, Syn and Load Events

### **Streaming.record\_module\_init**

**Streaming.record\_module\_init(*name*, *init\_var*)**

Record the variable requests from modules

**Streaming.send\_init**

Streaming.**send\_init**(*recepient='all'*)

Broadcast *Varheader*, *Idxvgs* and *SysParam* to all DiME clients after power flow routine

**Streaming.sync\_and\_handle**

Streaming.**sync\_and\_handle**()

Sync until the queue is empty. Handle sync'ed commands.

**Streaming.transpose\_matlab\_row**

**static** Streaming.**transpose\_matlab\_row**(*a*)

**Streaming.vars\_to\_modules**

Streaming.**vars\_to\_modules**()

Stream the results from the last step to modules

**Returns** None

**Streaming.vars\_to\_pmu**

Streaming.**vars\_to\_pmu**()

Broadcast all PMU measurements and BusFreq measurements in the variable *pmudata*

**andes.io.txt****Functions**

---

*dump\_data*(text, header, rowname, data, file)

---

## dump\_data

`andes.io.txt.dump_data(text, header, rowname, data, file, width=18, precision=5)`

## andes.io.xlsx

Excel reader and writer for ANDES power system parameters

This module utilizes openpyxl, xlswriter and pandas.DataFrame.

While I like the simplicity of the dome format, spreadsheets are easier to view and edit.

## Functions

---

<code>read(system, infile)</code>	Read an xlsx file with ANDES model data into an empty system
<hr/>	
<code>testlines(infile)</code>	
<hr/>	
<code>write(system, outfile[, skip_empty, ...])</code>	Write loaded ANDES system data into an xlsx file

---

## read

`andes.io.xlsx.read(system, infile)`

Read an xlsx file with ANDES model data into an empty system

### Parameters

**system** [System] Empty System instance

**infile** [str or file-like] Path to the input file, or a file-like object

### Returns

**System** System instance after succeeded

## testlines

`andes.io.xlsx.testlines(infile)`

## write

`andes.io.xlsx.write(system, outfile, skip_empty=True, overwrite=None, add_book=None, **kwargs)`  
 Write loaded ANDES system data into an xlsx file

### Parameters

- system** [System] A loaded system with parameters
- outfile** [str] Path to the output file
- skip\_empty** [bool] Skip output of empty models (n = 0)
- overwrite** [bool, optional] None to prompt for overwrite selection; True to overwrite; False to not overwrite
- add\_book** [str, optional] An optional model to be added to the output spreadsheet

### Returns

- bool** True if file written; False otherwise

## 5.5 Others

<code>andes.cli</code>	ANDES command-line interface and argument parsers.
<code>andes.main</code>	
<code>andes.utils.paths</code>	Utility functions for loading andes stock test cases
<code>andes.utils.snapshot</code>	Utility functions for saving and loading snapshots.
<code>andes.utils.widgets</code>	Support for Jupyter widgets.

### 5.5.1 andes.cli

ANDES command-line interface and argument parsers.

### Functions

<code>create_parser()</code>	The main level of command-line interface.
<code>main()</code>	Main command-line interface
<code>preamble()</code>	Log the ANDES command-line preamble at the <code>logging.INFO</code> level
<code>versioninfo()</code>	Print version info for ANDES and dependencies.

## create\_parser

`andes.cli.create_parser()`

The main level of command-line interface.

## main

`andes.cli.main()`

Main command-line interface

## preamble

`andes.cli.preamble()`

Log the ANDES command-line preamble at the *logging.INFO* level

## versioninfo

`andes.cli.versioninfo()`

Print version info for ANDES and dependencies.

## 5.5.2 andes.main

### Functions

<code>config_logger([stream, file, stream_level, ...])</code>	Configure an ANDES logger with a <i>FileHandler</i> and a <i>StreamHandler</i> .
<code>demo(**kwargs)</code>	TODO: show some demonstrations from CLI.
<code>doc([attribute, list_supported, config])</code>	Quick documentation from command-line.
<code>edit_conf([edit_config])</code>	Edit the Andes config file which occurs first in the search path.
<code>find_log_path(lg)</code>	Find the file paths of the FileHandlers.
<code>load(case[, codegen, setup, use_input_path])</code>	Load a case and set up a system without running routine.
<code>misc([edit_config, save_config, ...])</code>	Miscellaneous commands.
<code>plot(**kwargs)</code>	Wrapper for the plot tool.
<code>prepare([quick, incremental, models, ...])</code>	Run code generation.
<code>print_license()</code>	Print out Andes license to stdout.
<code>remove_output([recursive])</code>	Remove the outputs generated by Andes, including power flow reports <code>_out.txt</code> , time-domain list <code>_out.lst</code> and data <code>_out.dat</code> , eigenvalue analysis report <code>_eig.txt</code> .
<code>run(filename[, input_path, verbose, ...])</code>	Entry point to run ANDES routines.
<code>run_case(case, *[, routine, profile, ...])</code>	Run single simulation case for the given full path.

continues on next page

Table 43 – continued from previous page

<code>save_conf([config_path, overwrite])</code>	Save the Andes config to a file at the path specified by <code>save_config</code> .
<code>selftest([quick])</code>	Run unit tests.
<code>set_logger_level(lg, type_to_set, level)</code>	Set logging level for the given type of handler.

## config\_logger

`andes.main.config_logger(stream=True, file=True, stream_level=20, log_file='andes.log', log_path=None, file_level=10)`

Configure an ANDES logger with a *FileHandler* and a *StreamHandler*.

This function is called at the beginning of `andes.main.main()`. Updating `stream_level` and `file_level` is now supported.

### Parameters

**stream** [bool, optional] Create a *StreamHandler* for *stdout* if `True`. If `False`, the handler will not be created.

**file** [bool, optional] True if logging to `log_file`.

**log\_file** [str, optional] Log file name for *FileHandler*, 'andes.log' by default. If `None`, the *FileHandler* will not be created.

**log\_path** [str, optional] Path to store the log file. By default, the path is generated by `get_log_dir()` in `utils.misc`.

**stream\_level** [{10, 20, 30, 40, 50}, optional] *StreamHandler* verbosity level.

**file\_level** [{10, 20, 30, 40, 50}, optional] *FileHandler* verbosity level.

### Returns

-----

None

## demo

`andes.main.demo(**kwargs)`

TODO: show some demonstrations from CLI.

## doc

`andes.main.doc(attribute=None, list_supported=False, config=False, **kwargs)`  
Quick documentation from command-line.

## edit\_conf

`andes.main.edit_conf(edit_config: Optional[Union[str, bool]] = "")`  
Edit the Andes config file which occurs first in the search path.

### Parameters

**edit\_config** [bool] If True, try to open up an editor and edit the config file. Otherwise returns.

### Returns

**bool** True is a config file is found and an editor is opened. False if `edit_config` is False.

## find\_log\_path

`andes.main.find_log_path(lg)`  
Find the file paths of the FileHandlers.

## load

`andes.main.load(case, codegen=False, setup=True, use_input_path=True, **kwargs)`  
Load a case and set up a system without running routine. Return a system.  
Takes other kwargs recognizable by `System`, such as `addfile`, `input_path`, and `no_output`.

### Parameters

**case: str** Path to the test case

**codegen** [bool, optional] Call full `System.prepare` on the returned system. Set to True if one need to inspect pretty-print equations and run simulations.

**setup** [bool, optional] Call `System.setup` after loading

**use\_input\_path** [bool, optional] True to use the `input_path` argument to behave the same as `andes.main.run`.

**Warning:** If one need to add devices in addition to these from the case file, do `setup=False` and call `System.add()` to add devices. When done, manually invoke `setup()` to set up the system.

## misc

```
andes.main.misc(edit_config="", save_config="", show_license=False, clean=True, recursive=False,
               overwrite=None, **kwargs)
```

Miscellaneous commands.

## plot

```
andes.main.plot(**kwargs)
```

Wrapper for the plot tool.

## prepare

```
andes.main.prepare(quick=False, incremental=False, models=None, precompile=False, nomp=False,
                  **kwargs)
```

Run code generation.

### Parameters

**full** [bool] True to run full prep with formatted equations. Useful in interactive mode and during document generation.

**ncpu** [int] Number of cores to be used for parallel processing.

**cli** [bool] True to indicate running from CLI. It will set *quick* to True if not *full*.

**precompile** [bool] True to compile model function calls after code generation.

### Returns

System object if *cli* is *False*; *exit\_code 0* otherwise.

**Warning:** The default behavior has changed since v1.0.8: when *cli* is *True* and *full* is not *True*, quick code generation will be used.

## print\_license

```
andes.main.print_license()
```

Print out Andes license to stdout.

## remove\_output

`andes.main.remove_output(recursive=False)`

Remove the outputs generated by Andes, including power flow reports `_out.txt`, time-domain list `_out.lst` and data `_out.dat`, eigenvalue analysis report `_eig.txt`.

### Parameters

**recursive** [bool] Recursively clean all subfolders

### Returns

**bool** True is the function body executes with success. False otherwise.

## run

`andes.main.run(filename, input_path="", verbose=20, mp_verbose=30, ncpu=1, pool=False, cli=False, codegen=False, shell=False, **kwargs)`

Entry point to run ANDES routines.

### Parameters

**filename** [str] file name (or pattern)

**input\_path** [str, optional] input search path

**verbose** [int, 10 (DEBUG), 20 (INFO), 30 (WARNING), 40 (ERROR), 50 (CRITICAL)] Verbosity level. If `config_logger` is called prior to `run`, this option will be ignored.

**mp\_verbose** [int] Verbosity level for multiprocessing tasks

**ncpu** [int, optional] Number of cpu cores to use in parallel

**pool: bool, optional** Use Pool for multiprocessing to return a list of created Systems.

**kwargs** Other supported keyword arguments

**cli** [bool, optional] If is running from command-line. If True, returns exit code instead of System

**codegen** [bool, optional] Run full code generation for System before loading case. Only used for single test case.

**shell** [bool, optional] If True, enter IPython shell after routine.

### Returns

**System or exit\_code** An instance of system (if `cli == False`) or an exit code otherwise..

## run\_case

```
andes.main.run_case(case, *, routine='pflow', profile=False, convert="", convert_all="",
                   add_book=None, codegen=False, remove_pycapsule=False, **kwargs)
```

Run single simulation case for the given full path. Use `run` instead of `run_case` whenever possible.

Argument `input_path` will not be prepended to `case`.

Arguments recognizable by `load` can be passed to `run_case`.

### Parameters

**case** [str] Full path to the test case

**routine** [str, ('pflow', 'tds', 'eig')] Computation routine to run

**profile** [bool, optional] True to enable profiler

**convert** [str, optional] Format name for case file conversion.

**convert\_all** [str, optional] Format name for case file conversion, output sheets for all available devices.

**add\_book** [str, optional] Name of the device to be added to an excel case as a new sheet.

**codegen** [bool, optional] True to run codegen

**remove\_pycapsule** [bool, optional] True to remove pycapsule from C libraries. Useful when dill serialization is needed.

## save\_conf

```
andes.main.save_conf(config_path=None, overwrite=None, **kwargs)
```

Save the Andes config to a file at the path specified by `save_config`. The save action will not run if `save_config = ''`.

### Parameters

**config\_path** [None or str, optional, (" by default)] Path to the file to save the config file. If the path is an empty string, the save action will not run. Save to `~/andes/andes.conf` if `None`.

### Returns

**bool** True is the save action is run. False otherwise.

## selftest

`andes.main.selftest(quick=False, **kwargs)`

Run unit tests.

## set\_logger\_level

`andes.main.set_logger_level(lg, type_to_set, level)`

Set logging level for the given type of handler.

## 5.5.3 andes.utils.paths

Utility functions for loading andes stock test cases

### Functions

<code>andes_root()</code>	Return the root path to the andes source code.
<code>cases_root()</code>	Return the root path to the stock cases
<code>confirm_overwrite(outfile[, overwrite])</code>	
<code>get_case(rpath[, check])</code>	Return the path to a stock case for a given path relative to andes/cases.
<code>get_config_path([file_name])</code>	Return the path of the config file to be loaded.
<code>get_dot_andes_path()</code>	Return the path to <HomeDir>/.andes
<code>get_log_dir()</code>	Get the directory for log file.
<code>get_pkl_path()</code>	Get the path to the picked/dilled function calls.
<code>get_pycode_path([pycode_path, mkdir])</code>	Get the path to the pycode folder.
<code>list_cases([rpath, no_print])</code>	List stock cases under a given folder relative to andes/cases
<code>tests_root()</code>	Return the root path to the stock cases

## andes\_root

`andes.utils.paths.andes_root()`

Return the root path to the andes source code.

### **cases\_root**

`andes.utils.paths.cases_root()`

Return the root path to the stock cases

### **confirm\_overwrite**

`andes.utils.paths.confirm_overwrite(outfile, overwrite=None)`

### **get\_case**

`andes.utils.paths.get_case(rpath, check=True)`

Return the path to a stock case for a given path relative to `andes/cases`.

To list all cases, use `andes.list_cases()`.

#### **Parameters**

**check** [bool] True to check if file exists

#### **Examples**

To get the path to the case *kundur\_full.xlsx* under folder *kundur*, do

```
andes.get_case('kundur/kundur_full.xlsx')
```

### **get\_config\_path**

`andes.utils.paths.get_config_path(file_name='andes.rc')`

Return the path of the config file to be loaded.

Search Priority: 1. current directory; 2. home directory.

#### **Parameters**

**file\_name** [str, optional] Config file name with the default as `andes.rc`.

#### **Returns**

Config path in string if found; None otherwise.

### **get\_dot\_andes\_path**

`andes.utils.paths.get_dot_andes_path()`

Return the path to <HomeDir>/.*andes*

### **get\_log\_dir**

`andes.utils.paths.get_log_dir()`

Get the directory for log file.

The default is <tempdir>/*andes*, where <tempdir> is provided by `tempfile.gettempdir()`.

#### **Returns**

**str** The path to the temporary logging directory

### **get\_pkl\_path**

`andes.utils.paths.get_pkl_path()`

Get the path to the pickled/dilled function calls.

#### **Returns**

**str** Path to the *calls.pkl* file

### **get\_pycode\_path**

`andes.utils.paths.get_pycode_path(pycode_path=None, mkdir=False)`

Get the path to the pycode folder.

### **list\_cases**

`andes.utils.paths.list_cases(rpath='.', no_print=False)`

List stock cases under a given folder relative to *andes/cases*

### **tests\_root**

`andes.utils.paths.tests_root()`

Return the root path to the stock cases

## Classes

---

*DisplayablePath*(path, parent\_path, is\_last)

---

### andes.utils.paths.DisplayablePath

**class** andes.utils.paths.**DisplayablePath**(path, parent\_path, is\_last)  
     **\_\_init\_\_**(path, parent\_path, is\_last)

#### Methods

---

*displayable*()

---

---

*make\_tree*(root[, parent, is\_last, criteria])

---

#### DisplayablePath.displayable

DisplayablePath.**displayable**()

#### DisplayablePath.make\_tree

**classmethod** DisplayablePath.**make\_tree**(root, parent=None, is\_last=False, criteria=None)

#### Attributes

---

*display\_filename\_prefix\_last*

---

---

*display\_filename\_prefix\_middle*

---

---

*display\_parent\_prefix\_last*

---

---

*display\_parent\_prefix\_middle*

---

---

*displayname*

---

**DisplayablePath.display\_filename\_prefix\_last**

```
DisplayablePath.display_filename_prefix_last = '└─'
```

**DisplayablePath.display\_filename\_prefix\_middle**

```
DisplayablePath.display_filename_prefix_middle = '├─'
```

**DisplayablePath.display\_parent\_prefix\_last**

```
DisplayablePath.display_parent_prefix_last = '│ '
```

**DisplayablePath.display\_parent\_prefix\_middle**

```
DisplayablePath.display_parent_prefix_middle = ' '
```

**DisplayablePath.displayname**

```
property DisplayablePath.displayname
```

## 5.5.4 andes.utils.snapshot

Utility functions for saving and loading snapshots.

### Functions

---

<code>load_ss(path)</code>	Load an ANDES snapshot and return a System object.
<code>save_ss(path, system)</code>	Save a system with all internal states as a snapshot.

---

### load\_ss

`andes.utils.snapshot.load_ss(path)`

Load an ANDES snapshot and return a System object.

**save\_ss**

`andes.utils.snapshot.save_ss(path, system)`

Save a system with all internal states as a snapshot.

**Returns**

**Path to the saved snapshot.**

**Warning:** One limitation of the current implementation is version dependency. The snapshots only work with the specific ANDES version that created it.

**5.5.5 andes.utils.widgets**

Support for Jupyter widgets.

Please manually install the following dependencies:

- ipywidgets
- ipysheet

If you are using JupyterLab, do

```
jupyter labextension install @jupyter-widgets/jupyterlab-manager
```

**Functions**

<code>edit_sheet(system, model)</code>	Use ipysheet to edit parameters of one model.
<code>edit_system(system)</code>	Edit a loaded ANDES System with ipywidgets.
<code>on_close(b)</code>	Callback for the Close button.
<code>on_update(b)</code>	Callback for the Update button.

**edit\_sheet**

`andes.utils.widgets.edit_sheet(system, model: str)`

Use ipysheet to edit parameters of one model.

### **edit\_system**

`andes.utils.widgets.edit_system(system)`

Edit a loaded ANDES System with ipywidgets.

### **on\_close**

`andes.utils.widgets.on_close(b)`

Callback for the Close button. Closes ipywidget objects.

### **on\_update**

`andes.utils.widgets.on_update(b)`

Callback for the Update button. Sets new parameters back to System.

## RELEASE NOTES

The APIs before v3.0.0 are in beta and may change without prior notice.

### 6.1 v1.6 Notes

#### 6.1.1 v1.6.0 (2022-03-11)

- Migrated documentation to the pydata template.
- Added compatibility with SymPy 1.9 and 1.10.

### 6.2 v1.5 Notes

#### 6.2.1 v1.5.12 (2022-03-05)

- Improved PSS/E parsers for WTDTA1 model to follow PSS/E parameter definition.
- Included the Jupyter notebook examples in the documentation.
- Tweaks to the plot utility.

#### 6.2.2 v1.5.11 (2022-02-23)

- Reduced the tolerance for tiny variable increments to be treated as zero.
- Fixed PSS/E parsers for renewable models.
- Minor renewable model fixes.

### 6.2.3 v1.5.10 (2022-02-01)

- Fixed one equation in *REGC\_A*.

### 6.2.4 v1.5.9 (2022-01-31)

- Added PLL1, a simple PLL model.
- Renamed REGCVSG to REGCV1 and REGCVSG2 to REGCV2.
- Added an alias list for model names. See `models/__init__.py`.
- Multiprocessing now executes on all CPUs that are physical, instead of logical. A new package `psutil` needs to be installed.
- Use of `Selector` is deprecated.

### 6.2.5 v1.5.8 (2021-12-21)

- Full initialization debug message will be printed only when `-v 10` and `run --init` are both used.
- Improved warning of out-of-limit initialization. Variables initialized at limits will be shown only at the debug level.
- Initialization improvements for models *REGCA1* and *REECA1*.
- Added model *HYGOV*.
- Changed the default *vout* of offline exciters to zeros. All *vout* equations need to be multiplied by *ue*.

### 6.2.6 v1.5.7 (2021-12-11)

This minor release highlights the improved debugging of initialization.

Highly verbose initialization output can be enabled when the verbose level is 10 or less. For example,

```
andes -v 10 run test.xlsx -r tds --init
```

will set the verbose level to 10 and run `test.xlsx` in the current folder, proceed to time-domain simulation but only initialize the models. Outputs will be printed to the shell where the command is executed.

To save the output to a file, use the following in a UNIX shell:

```
andes -v 10 run test.xlsx -r tds --init > info.txt 2>&1
```

where the first `>` pipes the output to a file named `info.txt`, and `2>&1` appends stderr (2) to stdout (1).

The other main improvement is allowing automatic limit adjustment during initialization. Due to parameter errors, some variables will be initialized to values outside the given limits. Most commercial software does not attempt to fix the parameter but rather adjust the limit in run time.

The same approach is followed in ANDES by automatically adjusting the upper limit, if exceeded, to variable initial values. The lower limit, however, is kept unadjusted by default.

Discrete components now take an argument named `allow_adjust` so that the model developer can specify if its limits can be adjusted or must be kept as is. Each model is allowed to specify three config flags to customize runtime behaviors: `allow_adjust`, `adjust_lower`, and `adjust_upper`. By default, `allow_adjust=True`, `adjust_upper=True`, and `adjust_lower=False`. One can modify the config file to enable or disable the limit adjustments for specific models.

Other fixes include:

- Bug fixes for GAST parameter AT.
- Bug fixes for IEEE3, GAST, ESAC1A and ESST1A when device is off to avoid matrix singularity.

### 6.2.7 v1.5.6 (2021-11-25)

- Allow specifying config options through command-line arguments `--config-option`.
- Added a voltage and frequency playback model PLBVFU1.
- Bug fixes to an SEXS equation.

### 6.2.8 v1.5.5 (2021-11-13)

- Added a *Timeseries* model for reading timeseries data from `xlsx`.
- Converted several models into Python packages.
- Bug fixes to TGOV1 equations (#226)

### 6.2.9 v1.5.4 (2021-11-02)

- Fixed a bug in generated `select` functions that omitted the coefficients of `__ones`.

### 6.2.10 v1.5.3 (2021-10-31)

- Reversed special arguments for the generated `select` function.
- Stabilized the argument list of pycode. If the pycode is identical to existing ones, the existing file will not be overwritten. As a result, compiled code is fully cached.
- Partially separated time-domain integration method into `daeint.py`.

### 6.2.11 v1.5.2 (2021-10-27)

- Removed CVXOPT dependency.
- Removed `__zeros` and `__ones` as they are no longer needed.
- Added `andes prep -c` to precompile the generated code.
- Added utility functions for saving and loading system snapshots. See `andes/utils/snapshot.py`.
- Compiled numba code is always cached.
- Bug fixes.

### 6.2.12 v1.5.1 (2021-10-23)

- Restored compatibility with SymPy 1.6.
- Added a group for voltage compensators.
- New models: IEEEVC and GAST.

### 6.2.13 v1.5.0 (2021-10-13)

- Support numba just-in-time compilation of all equation and Jacobian calls.

This option accelerates simulations by up to 30%. The acceleration is visible in medium-scale systems with multiple models. Such systems involve heavy function calls but a rather moderate load for linear equation solvers. The speed up is less significant in large-scale systems where solving equations is the major time consumer.

Numba is required and can be installed with `pip install numba` or `conda install numba`.

To turn on numba for ANDES, in the ANDES configuration under `[System]`, set `numba = 1` and `numba_cache = 1`.

The just-in-time compilation will compile the code upon the first execution based on the input types. When compilation is triggered, ANDES may appear frozen due to the compilation lag. The option `numba_cache = 1` will cache compiled machine code, so that the lag only occurs once until the next `andes prep`.

- Allow `BackRef` to populate to models through `Group`.

When model *A* stores an `IdxParam` pointing to a group, if `BackRef` with the name *A* are declared in both the group and the model, both `BackRef` will retrieve the backward references from model *A*.

- Allow `BaseVar` to accept partial initializations.

If `BaseVar.v_str_add = True`, the value of `v_str` will be added in place to variable value. An example is that voltage compensator sets part of the input voltage, and exciter reads the bus voltage. Exciter has `v.v_str_add = True` so that when compensators exist, the input voltage will be bus voltage (`vbus`) plus (`Eterm - vbus`). If no compensator exists, exciter will use bus voltages and function as expected.

- Added reserved variable names `__ones` and `__zeros` for ones and zeros with length equal to the device number.

`__ones` and `__zeros` are useful for vectorizing `choicelist` in Piecewise functions.

## 6.3 v1.4 Notes

### 6.3.1 v1.4.4 (2021-10-05)

- Bug fixes for refreshing generated code.

### 6.3.2 v1.4.3 (2021-09-25)

This release features parallel processing that cuts the time for `andes prepare` by more than half.

- `andes prepare` supports multiprocessing and uses it by default.
- Added aliases `andes st` and `andes prep` for `andes selftest` and `andes prepare`.
- `andes.config_logger` supports setting new `stream_level` and `file_level`.

New exciter models are contributed by Jinning Wang.

- Added AC8B, IEEE T3 and ESAC1A.

Other changes include disallowing numba's `nopython` mode.

### 6.3.3 v1.4.2 (2021-09-12)

- Bug fixes
- Dropped support for `cvxoptklu`.

### 6.3.4 v1.4.1 (2021-09-12)

- Bug fixes.
- Overhaul of the `prepare` and `undill` methods.
- `andes prepare` can be called for specific models through `-m`, which takes one or many model names as arguments.

### 6.3.5 v1.4.0 (2021-09-08)

This release highlights the distributed energy resource protection model.

- Added DGPRCT1 model to provide DG models with voltage- and frequency-based protection following IEEE 1547-2018.
- REECA1E supports frequency droop on power.
- Throws `TypeError` if type mismatches when using `ExtAlgeb` and `ExtState`.

## 6.4 v1.3 Notes

### 6.4.1 v1.3.12 (2021-08-22)

Plot enhancements:

- `plot()` takes an argument `mark` for masking y-axis data based on the `left` and `right` range parameters.
- `TDS.plt` provides a `panoview` method for plotting an panoramic view for selected variables and devices of a model.

Models:

- Added WIP EV models and protection models.

Test case: - Added CURENT EI test system. - Added a number of IEEE 14 bus test systems for specific models.

### 6.4.2 v1.3.11 (2021-07-27)

- Added REECA1E model with inertia emulation.
- Fixed an issue where the `vtype` of services was ignored.
- Changed default DPI for plotting to 100.

### 6.4.3 v1.3.10 (2021-06-08)

- Bug fixes for controllers when generators are off.

### 6.4.4 v1.3.9 (2021-06-02)

- Bug fixes in exciters when generators are offline.
- Added `safe_div` function for initialization equations.

### 6.4.5 v1.3.8 (2021-06-02)

- Added REGCVSG model for voltage-source controlled renewables.
- Turbine governors are now aware of the generator connection status.

#### 6.4.6 v1.3.7 (2021-05-03)

- Allow manually specifying variables needing initialization preceding a variable. Specify a list of variable names through `BaseVar.deps`.

#### 6.4.7 v1.3.6 (2021-04-23)

- Patched ESD1 model. Converted *distributed.py* into a package.
- Bug fixes.

#### 6.4.8 v1.3.5 (2021-03-20)

- Fixed a bug in connectivity check when bus 0 is islanded.
- Updated notebook examples.
- Updated tutorials.

#### 6.4.9 v1.3.4 (2021-03-13)

- Fixed a bug for the generated renewable energy code.

#### 6.4.10 v1.3.2 (2021-03-08)

- Relaxed the version requirements for NumPy and SymPy.

#### 6.4.11 v1.3.1 (2021-03-07)

- Writes all generated Python code to `~/ .andes/pycode` by default.
- Uses generated Python code by default instead of *calls.pkl*.
- Works with NumPy 1.20; works on Apple Silicon (use *miniforge*) to install native Python and NumPy for Apple Silicon.
- Generalized model initialization: automatically determines the initialization sequence and solve equations iteratively when necessary.
- In *System.config*, *save\_pycode* and *use\_pycode* are now deprecated.

### 6.4.12 v1.3.0 (2021-02-20)

- Allow *State* variable set *check\_init=False* to skip initialization test. One use case is for integrators with non-zero inputs (such as state-of-charge integration).
- Solves power flow for systems with multiple areas, each with one Slack generator.
- Added *Jumper* for connecting two buses with zero impedance.
- *REGCA1* and synchronous generators can take power ratio parameters *gammap* and *gammaq*.
- New models: *IEESGO* and *IEEET1*, *EXAC4*.
- Refactored exciters, turbine governors, and renewable models into modules.

## 6.5 v1.2 Notes

### 6.5.1 v1.2.9 (2021-01-16)

- Added system connectivity check for islanded buses.
- Depend on *openpyxl* for reading excel files since *xlrd* dropped support for any format but *xlsx* since v2.0.0.

### 6.5.2 v1.2.7 (2020-12-08)

- Time-domain integration now evaluates anti-windup limiter before algebraic residuals. It assures that algebraic residuals are calculated with the new state values if pegged at limits.
- Fixed the conditions for *Iq* ramping in *REGC*; removed *Iqmax* and *Iqmin*.
- Added a new plot function *plotn* to allow multiple subplots in one figure.
- *TDS.config.g\_scale* is now used as a factor for scaling algebraic equations for better convergence. Setting it to 1.0 functions the same as before.

### 6.5.3 v1.2.6 (2020-12-01)

- Added *TGOVIN* model which sums *pref* and *paux* after the 1/droop block.
- Added *ZIP* and *FLoad* for dynamic analysis. Need to be initialized after power flow.
- Added *DAETimeSeries.get\_data()* method.
- Added IEEE 14-bus test cases with solar PV (*ieee14\_solar.xlsx*) and Generic Type 3 wind (*ieee14\_wt3.xlsx*).

### 6.5.4 v1.2.5 (2020-11-19)

- Added *Summary* model to allow arbitrary information for a test case. Works in *xlsx* and *json* formats.
- PV reactive power limit works. Automatically determines the number of PVs to convert if  $npv2pq=0$ .
- Limiter and AntiWindup limiter can use  $sign\_upper=-1$  and  $sign\_lower=-1$  to negate the provided limits.
- Improved error messages for inconsistent data.
- *DAETimeSeries* functions refactored.

### 6.5.5 v1.2.4 (2020-11-13)

- Added switched shunt class *ShuntSw*.
- BaseParam takes *invert* and *oconvert* for converting parameter elements from and to files.

### 6.5.6 v1.2.3 (2020-11-02)

- Support variable *sys\_mva* (system base mva) in equation strings.
- Default support for KVOPT through pip installation.

### 6.5.7 v1.2.2 (2020-11-01)

New Models:

- PVD1 model, WECC distributed PV model. Supports multiple PVD1 devices on the same bus.
- Added ACEc model, ACE calculation with continuous freq.

Changes and fixes:

- Renamed *TDS.\_itm\_step* to *TDS.itm\_step* as a public API.
- Allow variable *sys\_f* (system frequency) in equation strings.
- Fixed ACE equation. measurement.
- Support *kvxopt* as a drop-in replacement for *cvxopt* to bring KLU to Windows (and other platforms).
- Added *kvxopt* as a dependency for PyPI installation.

### 6.5.8 v1.2.1 (2020-10-11)

- Renamed *models.non\_jit* to *models.file\_classes*.
- Removed *models/jit.py* as models have to be loaded and instantiated anyway before undill.
- Skip generating empty equation calls.

### 6.5.9 v1.2.0 (2020-10-10)

This version contains major refactor for speed improvement.

- Refactored Jacobian calls generation so that for each model, one call is generated for each Jacobian type.
- Refactored Service equation generation so that the exact arguments are passed.

Also contains an experimental Python code dump function.

- Controlled in `System.config`, one can turn on `save_pycode` to dump equation and Jacobian calls to `~/ .andes/pycode`. Requires one call to `andes prepare`.
- The Python code dump can be reformatted with `yapf` through the config option `yapf_pycode`. Requires separate installation.
- The dumped Python code can be used for subsequent simulations through the config option `use_pycode`.

## 6.6 v1.1 Notes

### 6.6.1 v1.1.5 (2020-10-08)

- Allow plotting to existing axes with the same plot API.
- Added TGOV1DB model (TGOV1 with an input dead-band).
- Added an experimental numba support.
- Patched *LazyImport* for a snappier command-line interface.
- `andes selftest -q` now skips code generation.

### 6.6.2 v1.1.4 (2020-09-22)

- Support *BackRef* for groups.
- Added CLI `--pool` to use `multiprocess.Pool` for multiple cases. When combined with `--shell`, `--pool` returns System Objects in the list `system`.
- Fixed bugs and improved manual.

### 6.6.3 v1.1.3 (2020-09-05)

- Improved documentation.
- Minor bug fixes.

### 6.6.4 v1.1.2 (2020-09-03)

- Patched time-domain for continuing simulation.

### 6.6.5 v1.1.1 (2020-09-02)

- Added back quasi-real-time speed control through `--qrt` and `--kqrt KQRT`.
- Patched the time-domain routine for the final step.

### 6.6.6 v1.1.0 (2020-09-01)

- Defaulted *BaseVar.diag\_eps* to *System.Config.diag\_eps*.
- Added option *TDS.config.g\_scale* to allow for scaling the algebraic mismatch with step size.
- Added induction motor models *Motor3* and *Motor5* (PSAT models).
- Allow a PFlow-TDS model to skip TDS initialization by setting *ModelFlags.tds\_init* to False.
- Added Motor models *Motor3* and *Motor5*.
- Imported *get\_case* and *list\_cases* to the root package level.
- Added test cases (Kundur's system) with wind.

Added Generic Type 3 wind turbine component models:

- Drive-train models *WTDTA1* (dual-mass model) and *WTDS* (single-mass model).
- Aerodynamic model *WTARA1*.
- Pitch controller model *WTPTA1*.
- Torque (a.k.a. Pref) model *WTTQA1*.

## 6.7 v1.0 Notes

### 6.7.1 v1.0.8 (2020-07-29)

New features and models:

- Added renewable energy models *REECA1* and *REPCA1*.
- Added service *EventFlag* which automatically calls events if its input changes.

- Added service *ExtendedEvent* which flags an extended event for a given time.
- Added service *ApplyFunc* to apply a numeric function. For the most cases where one would need *ApplyFunc*, consider using *ConstService* first.
- Allow *selftest -q* for quick selftest by skipping codegen.
- Improved time stepping logic and convergence tests.
- Updated examples.

Default behavior changes include:

- `andes prepare` now takes three mutually exclusive arguments, *full*, *quick* and *incremental*. The command-line now defaults to the quick mode. `andes.prepare()` still uses the full mode.
- `Model.s_update` now evaluates the generated and the user-provided calls in sequence for each service in order.
- Renamed model *REGCAU1* to *REGCA1*.

### 6.7.2 v1.0.7 (2020-07-18)

- Use in-place assignment when updating Jacobian values in Triplets.
- Patched a major but simple bug where the Jacobian refactorization flag is set to the wrong place.
- New models: PMU, REGCAU1 (tests pending).
- New blocks: DeadBand1, PIFreeze, PITrackAW, PITrackAWFreeze (tests pending), and LagFreeze (tests pending).
- *andes plot* supports dashed horizontal and vertical lines through *hline1*, *hline2*, *vline1* and *vline2*.
- Discrete: renamed *DeadBand* to *DeadBandRT* (deadband with return).
- Service: renamed *FlagNotNone* to *FlagValue* with an option to flip the flags.
- Other tweaks.

### 6.7.3 v1.0.6 (2020-07-08)

- Patched step size adjustment algorithm.
- Added Area Control Error (ACE) model.

#### 6.7.4 v1.0.5 (2020-07-02)

- Minor bug fixes for service initialization.
- Added a wrapper to call `TDS.fg_update` to allow passing variables from caller.
- Added pre-event time to the `switch_times`.

#### 6.7.5 v1.0.4 (2020-06-26)

- Implemented compressed NumPy format (npz) for time-domain simulation output data file.
- Implemented optional attribute *vtype* for specifying data type for Service.
- Patched COI speed initialization.
- Patched PSS/E parser for two-winding transformer winding and impedance modes.

#### 6.7.6 v1.0.3 (2020-06-02)

- Patches *PQ* model equations where the "or" logic "|" is ignored in equation strings. To adjust PQ load in time domain simulation, refer to the note in *pq.py*.
- Allow *Model.alter* to update service values.

#### 6.7.7 v1.0.2 (2020-06-01)

- Patches the conda-forge script to use SymPy < 1.6. After SymPy version 1.5.1, comparison operations cannot be sympified. Pip installations are not affected.

#### 6.7.8 v1.0.1 (2020-05-27)

- Generate one lambda function for each of f and g, instead of generating one for each single f/g equation. Requires to run *andes prepare* after updating.

#### 6.7.9 v1.0.0 (2020-05-25)

This release is going to be tagged as v0.9.5 and later tagged as v1.0.0.

- Added verification results using IEEE 14-bus, NPCC, and WECC systems under folder *examples*.
- Patches GENROU and EXDC2 models.
- Updated test cases for WECC, NPCC IEEE 14-bus.
- Documentation improvements.
- Various tweaks.

## 6.8 Pre-v1.0.0

### 6.8.1 v0.9.4 (2020-05-20)

- Added exciter models EXST1, ESST3A, ESDC2A, SEXS, and IEEEEX1, turbine governor model IEEEG1 (dual-machine support), and stabilizer model ST2CUT.
- Added blocks HVGate and LVGate with a work-around for `sympy.maximum/minimum`.
- Added services *PostInitService* (for storing initialized values), and *VarService* (variable services that get updated) after limiters and before equations).
- Added service *InitChecker* for checking initialization values against typical values. Warnings will be issued when out of bound or equality/ inequality conditions are not met.
- Allow internal variables to be associated with a discrete component which will be updated before initialization (through *BaseVar.discrete*).
- Allow turbine governors to specify an optional *Tn* (turbine rating). If not provided, turbine rating will fall back to *Sn* (generator rating).
- Renamed *OptionalSelect* to *DataSelect*; Added *NumSelect*, the array-based version of *DataSelect*.
- Allow to regenerate code for updated models through `andes prepare -qi`.
- Various patches to allow zeroing out time constants in transfer functions.

### 6.8.2 v0.9.3 (2020-05-05)

This version contains bug fixes and performance tweaks.

- Fixed an *AntiWindup* issue that causes variables to stuck at limits.
- Allow `TDS.run()` to resume from a stopped simulation and run to the new end time in `TDS.config.tf`.
- Improved TDS data dump speed by not constructing `DataFrame` by default.
- Added tests for *kundur\_full.xlsx* and *kundur\_aw.xlsx* to ensure results are the same as known values.
- Other bug fixes.

### 6.8.3 v0.9.1 (2020-05-02)

This version accelerates computations by about 35%.

- Models with flag `collate=False`, which is the new default, will slice DAE arrays for all internal vars to reduce copying back and forth.
- The change above greatly reduced computation time. For *kundur\_ieeeest.xlsx*, simulation time is down from 2.50 sec to 1.64 sec.

- The side-effects include a change in variable ordering in output lst file. It also eliminated the feasibility of evaluating model equations in parallel, which has not been implemented and does not seem promising in Python.
- Separated symbolic processor and documentation generator from Model into SymProcessor and Documenter classes.
- `andes prepare` now shows progress in the console.
- Store exit code in `System.exit_code` and returns to system when called from CLI.
- Refactored the solver interface.
- Patched `Config.check` for routines.
- SciPy Newton-Krylov power flow solver is no longer supported.
- Patched a bug in v0.9.0 related to *dae.Tf*.

#### 6.8.4 v0.8.8 (2020-04-28)

This update contains a quick but significant fix to boost the simulation speed by avoiding calls to empty user-defined numerical calls.

- In *Model.flags* and *Block.flags*, added *f\_num*, *g\_num* and *j\_num* to indicate if user-defined numerical calls exist.
- In *Model.f\_update*, *Model.g\_update* and *Model.j\_update*, check the above flags to avoid unnecessary calls to empty numeric functions.
- For the *kundur\_ieeest.xlsx* case, simulation time was reduced from 3.5s to 2.7s.

#### 6.8.5 v0.8.7 (2020-04-28)

- Changed *RefParam* to a service type called *BackRef*.
- Added *DeviceFinder*, a service type to find device idx when not provided. *DeviceFinder* will also automatically add devices if not found.
- Added *OptionalSelect*, a service type to select optional parameters if provided and select fallback ones otherwise.
- Added discrete types *Derivative*, *Delay*, and *Average*,
- Implemented full IEEEEST stabilizer.
- Implemented COI for generator speed and angle measurement.

### 6.8.6 v0.8.6 (2020-04-21)

This release contains important documentation fixes and two new blocks.

- Fixed documentations in *andes doc* to address a misplacement of symbols and equations.
- Converted all blocks to the division-free formulation (with *dae.zf* renamed to *dae.Tf*).
- Fixed equation errors in the block documentation.
- Implemented two new blocks: Lag2ndOrd and LeadLag2ndOrd.
- Added a prototype for IEEEEST stabilizer with some fixes needed.

### 6.8.7 v0.8.5 (2020-04-17)

- Converted the differential equations to the form of  $T \dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}, \mathbf{y})$ , where  $T$  is supplied to `t_const` of `State/ExtState`.
- Added the support for Config fields in documentation (in *andes doc* and on *readthedocs*).
- Added Config consistency checking.
- Converted *Model.idx* from a list to *DataParam*.
- Renamed the API of routines (summary, init, run, report).
- Automatically generated indices now start at 1 (i.e., "GENCLS\_1" is the first GENCLS device).
- Added test cases for WECC system. The model with classical generators is verified against TSAT.
- Minor features: *andes -v 1* for debug output with levels and line numbers.

### 6.8.8 v0.8.4 (2020-04-07)

- Added support for JSON case files. Convert existing case file to JSON with `--convert json`.
- Added support for PSS/E dyr files, loadable with `-addfile ADDFILE`.
- Added `andes plot --xargs` for searching variable name and plotting. See example 6.
- Various bug fixes: Fault power injection fix;

### 6.8.9 v0.8.3 (2020-03-25)

- Improved storage for Jacobian triplets (see `andes.core.triplet.JacTriplet`).
- On-the-fly parameter alteration for power flow calculations (`Model.alter` method).
- Exported frequently used functions to the root package (`andes.config_logger`, `andes.run`, `andes.prepare` and `andes.load`).
- Return a list of System objects when multiprocessing in an interactive environment.
- Exported classes to *andes.core*.

- Various bug fixes and documentation improvements.

#### **6.8.10 v0.8.0 (2020-02-12)**

- First release of the hybrid symbolic-numeric framework in ANDES.
- A new framework is used to describe DAE models, generate equation documentation, and generate code for numerical simulation.
- Models are written in the new framework. Supported models include GENCLS, GENROU, EXDC2, TGOV1, TG2
- PSS/E raw parser, MATPOWER parser, and ANDES xlsx parser.
- Newton-Raphson power flow, trapezoidal rule for numerical integration, and full eigenvalue analysis.

#### **6.8.11 v0.6.9 (2020-02-12)**

- Version 0.6.9 is the last version for the numeric-only modeling framework.
- This version will not be updated any more. But, models, routines and functions will be ported to the new version.
